Agents may be implemented in widely varying forms, ranging from simple event-response formalisms or state machines (where the specification translates directly into implementation) to complex AI architectures with the aspiration to model human behavior such as SOAR (Tambe et al., 1995). Brooks (1991) has argued that robots do not necessarily have to use cognitive functions, reasoning, or planning to behave efficiently and to appear intelligent, but that the selection of optimal features for sensors and effectors and simple rules governing the response and an appropriate architecture permits the implementation of robust and effective robots. The bottom-up composition of robots in a hierarchical fashion from separate components with their own independent behavior is called subsumption architecture, using, for example, legs comprising mechanical structures, sensors, and motors plus basic wiring that allows them to move independently, or a vision system that includes preprocessing and active control of the sensors as building blocks. The advantage of the subsumption architecture is that there is no need for a centralized representation of all sensor data, and complete planning of all behavior in detail. The central control system may be much smaller, and the behavior of the entire robot more robust. As components are combined, the resulting behavior becomes more complex and assumes behavior not designed into the components, which is often called emergent behavior. Agents, by analogy, would use existing data capture and analysis functions and initiate actions by calling other programs, and thus can be restricted to the decision-making algorithms that are the essence of the agent's behavior.

The combination of a form of learning with autonomy is highly attractive because the ability of the agent to adapt to changing environmental conditions further decreases the need for supervision and instruction by the owner, and increases the robustness of its behavior. In most instances simple forms of learning (adaptation of parameters) are used. More complex forms of learning (concept formation, elaboration of new response patterns based on planning) are hard to implement, require massive amounts of information, and are much less reliable and secure than preprogrammed responses. The ability to learn can have advantages, but also carries high cost during design and run-time.

Multiagent Systems and Cooperating Agents

Autonomous agents are robust due to their task-specific and encapsulated nature, but this also limits them to the particular tasks and contexts for which they are designed. As the functionality of an individual agent increases, the optimization effort and maintenance effort is likely to increase unproportionally. An alternative is to compose systems with complex behavior from a number of loosely coupled agents. As a result the robustness and reliability increase, local decision making using local data demands fewer central resources, and the need for communication between components decreases. The composition of large systems as a collection of agents is attractive because of the open architecture, where new agents can be added as required without the need to modify the existing system.

The behavior of a multiagent system is not specified in detail, and testing has to be done experimentally. Exhaustive tests of a full range of conditions are generally not possible; the behavior of multiagent systems is not verified for unforeseen states. This may be very relevant for systems in safety-critical applications, and systems with fluctuating load, such as communication, emergency, or trading systems.

Swarms are collections of autonomous communicating agents, such as swarms of birds or ant colonies. Characteristically swarms exhibit regular and sophisticated behavior without centralized command and control. The apparently intelligent behavior of the swarm is generated by individuals with limited rules and communication with close neighbors. Aspired applications are underwater exploration and monitoring, where the capabilities of a swarm are an alternative to large hierarchically controlled systems. The swarm is robust, can suffer some fatalities, and can adjust to restricted communication abilities as in deep sea.

Anthropomorphic and Mentalistic Concepts

Agents can be designed to mimic natural language, speech, and animations as output to human users (Babski and Thalmann, 2000). This can help users, but may also be irritating, and create the erroneous impression that human-like reasoning is included in the agent. Mentalistic concepts may also be used in the design of agent features, such as motivation, emotions, consciousness, or moods, to describe the internal state of the agent (Sloman, 1997). At this stage it may be best to consider these concepts as metaphors for some aspects of technical communication, but these functions do not model human communication or even human mental processes.

Applications for Autonomous Agents

Interesting application domains for agents are those where the relative strengths of agent technology can be used to augment or partly replace direct interaction of the human user with a software application. Where continuous monitoring of data streams, repeated quick responses to events, statistical analysis and pattern detection in large amounts of data, and fast access to databases are required, agents can respond faster and more reliably than humans. Web services are interesting domains for the use of agents because they provide access to large amounts of information, create the need to search and select data, and make it attractive to enable automatic responses, relieving the human user from routine tasks, and also to improve performance.

Agents in User Interfaces

Early implementations of user interface agents (Lieberman, 1997; Maes, 1994) observed user behavior, interpreted user requests, and explicitly suggested actions and the automation of routine functions, but it was found that users prefer less obtrusive functions. Today agent-like functions are included in many applications as hints, preselection of options, or corrections and auto-completion of user input. Rather than the agent control core, innovative user interfaces use sophisticated sensors, data and text analysis to produce user support. These functions are called assistants, for example in cars, where they produce warnings and information display based on information not easily accessible to the driver.

Help functions in user interfaces can include agents that analyze previous user input and provide specific help for the user in his or her application context. More specific performance support uses a database of procedures specific to, for example, a particular company, a complex technical device, or an application domain. Performance support consists of guiding users to select and carry out prescribed procedures, relieving the user from the need to memorize and practice these procedures previously, and also to standardize procedures and to reuse knowledge in an organization (Chin, 1991). Studies where users were asked to assess their subjective impression of agents indicate that users are pleased to receive active support in situations where they feel helpless, but they are easily irritated by verbose and redundant information when they have relatively mature knowledge of a domain. Agents should include strategies and thresholds for presenting information in adequate format.

Operators for safety-critical tasks such as power station control or piloting are trained extensively in simulators. Where the nature of the task includes cooperation with other individuals, these are implemented as agents, representing a wide array of human behavior (Tambe et al., 1995).

Information Filtering and Access

Agents to support user information search behavior employ a personalized profile that is continuously constructed and adapted based on this users search behavior, and on known search strategies and preferences of other users. Access to large amounts of information, for example, catalogs, the CD and book market or scientific publications, but also TV programs, can be supported by agents that use instructions from the user in the form of keywords, reference to relevant similar items, and user profiles elaborated from previous user requests to actively search and display information selectively.

Agents in Electronic Trade

In electronic trading systems agents replace human traders in the monitoring of market data and the execution of orders for purchases and sales. Agents provided with strategies based on mathematical models exceed the capabilities of human traders in a number of aspects: agents can supervise more information streams with high precision, and execute orders extremely fast. Software agents do not use approximations, common sense, rules of thumb, or gut feelings, and are not subject to sentiments. The programs that the agents execute are rational in the sense that they do not deviate from the programed strategy to optimize profit. Research on economic decisions has shown that human traders deviate systematically from this form of rational behavior. Experiments have shown that software agents with optimal strategies dominate human robot traders (DeLuca and Cliff, 2011).

As in other multiagent systems the impact of diverse strategies executed by a large number of independent agents for the behavior of the system are not easy to predict, especially the occurrence of extreme states and anomalies of the market, leading to crashes. The benefit expected from electronic markets is efficiency and transparency, but the risk of instability is a concern. The appropriate design of markets taking these aspects into account is a specialized area of research (Sandholm, 2000).

In an open e-commerce environment individual participants provide trading agents with extensive amounts of information about their behavior. Sales agents can use this information to optimize their sales tactic by directing offers toward the single customer that are adapted to the profile and inferred preference of the potential buyer.

Evaluation of Agent Performance

Agent performance is judged by the owner and user according to the advantages obtained from the agent. Most agents incur only minimal costs for storage and computing power but may have considerable costs for communication with other agents, their environment, and the user. The main advantage should be reduced communication effort for the user in instructing his or her systems to perform his or her tasks.

The bandwidth of user–agent communication should be much lower than the bandwidth required for direct user–application interaction. The quality of performance must also be considered. Quality criteria for the information obtained and for the decisions made by the user include the number of hits and errors compared to other ways of accessing the same information, the erroneous decisions made, and opportunities missed. Precise and detailed analyses of the benefit of agent applications are still scarce. In a number of regular competitions, applications based on agent technology for specific tasks compete and compare their relative performance (TAC; DARPA grand challenge; Robocup).

Ethical Considerations

Obviously in systems where humans and agents interact, there is a potential for agents to have an impact on humans and important affairs. These may cause disruptive economic events, breakdown and failure of vehicles in traffic, or threats emanating from security applications. The creation of market crashes by the dynamics of extremely fast automated trading is a subject of research and practical concern. The emergence of risky behavior, or the interlocking of security mechanisms presents obvious risks that may be caused by emergent

behavior of agent systems. The use of agents for decision making and execution of procedures in situations with life-threatening consequences for individuals is subject to the same considerations as in respect of the use of military robots (Lin et al., 2012).

Ownership of Personal Data and Privacy

Agents often observe and subsequently attempt to predict the behavior of humans. The ability to predict behavior is a precondition for influencing, and potentially a means for manipulating, user behavior. Robots, since their conception in the twentieth century, are postulated to have a built-in rule not to harm humans. Agents, however, are mediators of human-to-human communication. An agent represents the interests of an owner, and in this role may pursue goals that are in conflict with the interest of other humans. Because ethical behavior is hard to enforce universally by rules, users may want to be cautious against giving information to agent-based systems that are outside their control. This is a particularly relevant aspect for e-commerce where the integration of data-processing systems opens the possibility to test and model the status of partners and competitors, predict their behavior, and adapt their own strategy. When, for example, it can be observed that the production facilities of a supplier are not fully used, it is likely that lower prices can be negotiated. The ownership and control over personal data is thus a valuable asset and subject of legal considerations and economic competition.

Multiagent Systems as Models of the Behavior of Social Systems

In biological and social systems large assemblies of individuals often exhibit regular behavior without centralized command and control, such as swarms of birds. Agent models are used as models of such behavior, for example in traffic systems or markets. The challenge is to identify the design principles embedded in the relatively simple individual agents that generate highly complex, adaptive, and seemingly intelligent behavior of the entire swarm. The behavior in traffic (pedestrians or cars) has been modeled as agent systems, and rules that generate safer and more efficient traffic flow have been suggested (Kretz and Schreckenberg, 2006; Yu and Helbing, 2010). Of particular interest is the case in which autonomous vehicles are included in the stream of traffic composed of human drivers.

Grand Visions and the Ontological Incongruence between Agent Implementations and Biological Entities

The term autonomous agent was originally a grand vision associated with high ambitions, concentrating on interacting agent technology combined with sensors and effectors. The strong point of view of agent technology (e.g., Moravec, 1988) assumed that the expected further growth of computational power will help to automate most of human work within the lifetime of some of us, and even surpass human cognitive abilities. These visions should be viewed with caution: the ontological incongruence of the theories of natural and biological processes on the one hand, and the engineering principles for constructing autonomous and intelligent systems on the other hand may create a larger distance than anticipated. When the core concepts in the two domains are examined, an essential difference between theories of cognition and the design specifications for artificial intelligent systems becomes apparent: formal and mathematical theories of natural processes are understood to be abstractions of a qualitatively different reality; they are generally not assumed to be able to represent the entire essence of the processes modeled, not even when extended dramatically in size. Specifications of computational artifacts must be assumed to be self-contained and complete – they could not work otherwise and would be useless for applications. The terms used to describe mental processes, such as *emotions* or *consciousness*, are often only names to describe entities that we recognize when we see them, but do not yet understand sufficiently in a reductionist sense. These theories may mislead some to believe that implementing these theories as computing machines will produce the full behavior of the entities in question. If not hubris, the ambition to build humanlike, or even animal-like, intelligence still represents a goal that transcends today's realistic possibilities. Computational models prove to be valuable research tools, but not easy means to generate automata that are capable of complex behavior observed in reality.

Further Developments

The concept of agents is maturing and realized in the implementation of many applications that support humans in everyday tasks. It appears that the further development of agent technology and practical applications profits mainly from extended abilities to sense and analyze large amounts of diverse information, and to execute complex procedures with high speed and precision, rather than the implementation of more capable cognition-like capabilities for decision making.

Abstract

Individual autonomy is the property or capacity of agents of being self-governing or self-determining. An autonomous state is one in which a person's will is genuinely his or her own. This article outlines the main philosophical notions of autonomy under five headings: first, the traditional Kantian account; second, procedural accounts that claim that autonomy requires a kind of self-reflective authenticity; third, neo-Kantian analyses that introduce normative competence, or an ability to identify and apply moral or intersubjective norms; fourth, theories claiming that there are psychological conditions of autonomy, such as self-esteem, or the agent's sense of answerability for his or her own choices and preferences; and fifth, theories that introduce external moral or social conditions of autonomy.

Introduction

Individual autonomy is usually taken to be the property or capacity of agents of being self-governing or self-determining. Within the philosophical literature, 'autonomy' has been construed as a fundamental right, as a basic political good of liberal political theory, as a character ideal, and as a necessary condition of full moral agency. Although there are many different conceptions of autonomy, there is a common theme. An autonomous state is usually taken to mean one in which a person's will is genuinely his or her own.

Individual or agent autonomy (including moral autonomy) is to be distinguished from political autonomy. Political autonomy is a property of nations or states, and typically requires the absence of conditions that would undermine a nation's capacity for self-determination. A nation is self-governing or self-determining when it is not subject to interference or coercion by others. However, for an individual to be self-governing, certain positive conditions are required in addition to the absence of interference. Consider two typical failures of personal autonomy: first, agents who habitually and uncritically adopts others' social preferences and values as their own; and second, agents who have so internalized the outlooks and mores of the family in which they grew up that these are treated as authoritative without critical reflection (Feinberg, 1986: p. 32). Although in neither case is there any overt interference or coercion, agents in both cases lack autonomy because they fail to exhibit a characteristic necessary for autonomy – for example, a capacity for "subjecting these governing ideals to rational criticism and then modifying them when necessary" (Feinberg, 1986: p. 32). The development of such positive capacities can be undermined by social conditions including oppression, and therefore the articulation of a conception of autonomy is an important tool for feminists and other social critics (e.g., Meyers, 1989).

There are different classifications of theories of autonomy in the current philosophical literature. One approach is to divide theories of autonomy into procedural theories and substantive theories (Mackenzie and Stoljar, 2000b). Procedural theories claim that critical reflection is sufficient for autonomy: agents are autonomous when they reflect on their motivations, beliefs, and values in the right way. Procedural theories seek to define autonomy using morally neutral conditions such as reflective endorsement (Frankfurt, 1988; Dworkin, 1988; Friedman, 2003) or nonalienation (Christman, 2009). Substantive theories, however, build in moral or other normative conditions, for instance, moral attitudes to oneself or background moral conditions (Benson, 2005; Raz, 1986). Alternatively, theories of autonomy may be classified as either internalist or externalist. Procedural theories are internalist when they employ only internal psychological conditions to spell out autonomy; they are externalist when they require additional conditions that are external to agents' present internal psychological states, for instance, historical conditions (Mele, 1995). Other externalist theories employ the notion of morally adequate options (Raz, 1986) or 'sociorelational' conditions (Oshana, 2006). Since the latter externalist positions may also require a background moral theory to spell out precisely the external conditions that are incompatible with autonomy, these externalist theories are often substantive as well. Moreover, theories of autonomy distinguish between local and global conditions of autonomy. Many theorists focus on the conditions required for local autonomy, namely, what is required for particular choices, preferences, or desires at particular times to count as autonomous (e.g., Christman, 2009). Others focus on the conditions required for agents to achieve autonomy over an extended period and treat autonomy as a global condition of agents rather than a local feature of preferences and desires (e.g., Oshana, 2006).

This article describes the main philosophical notions of autonomy. The first section outlines the traditional Kantian account, which conceives of autonomy as an ability of rational agents to formulate universal moral principles. These moral principles are said to originate in the will of the agent and to be, in this sense, the agent's 'own.' The second section elaborates different procedural responses to the traditional Kantian account. These claim that what is required for autonomy is a kind of procedural authenticity, but each proposes a different conception of authenticity. The section briefly surveys three conceptions of authenticity: authenticity as endorsement or 'identification,' authenticity as nonalienation, and authenticity as self-discovery. The third section describes what could be called 'neo-Kantian' analyses of autonomy. These propose that autonomy requires 'normative competence,' namely, an ability

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63004-0

to identify and apply moral norms, or norms that are otherwise 'correct' for an agent to endorse. The fourth section identifies theories claiming that there are psychological conditions of autonomy in addition to processes of critical reflection. These conditions include either self-regarding attitudes such as those of self-trust and self-esteem or the agent's sense of answerability for his or her own choices and conduct. The final section briefly outlines theories that introduce external moral or social conditions on autonomy.

The Kantian Conception of Autonomy

A prominent strand within autonomy theory is derived from the philosophy of Immanuel Kant. For Kant, autonomy has a special meaning: "Autonomy of the will is the property the will has of being a law unto itself (independently of every property belonging to the objects of volition)" (1785/1948: p. 108). Rational beings make the moral law for themselves, and so can regard themselves as authors of the law. Thus, individual autonomy is manifested when rational agents 'will' the moral law. An important feature of the moral law is that it is a categorical, not a hypothetical, imperative. When agents formulate a categorical imperative, they formulate a maxim of the form 'I ought to do this,' not of the form 'I ought to do this if I desire that.' For example, agents formulate the moral law when they will 'I ought not to lie,' but formulate a hypothetical imperative when they will 'I ought not to lie if I desire not to be punished for lying.' The act of formulating the moral law is therefore an act of a pure autonomous will: it is untainted by the influence of the desires and interests that an agent may have relative to a particular situation. The pure autonomous will amounts to a metaphysical conception of the self, a self unconstrained by empirical desires, interests, and social forces. The traditional Kantian conception therefore presupposes a version of incompatibilism, namely, the thesis that free will cannot be reconciled with socialization or physical determinism.

A contemporary parallel of Kant's conception of autonomy is John Rawls's notion of free and rational agents formulating principles of justice in the 'original position' (Rawls, 1971). Rawls argues that rational agents formulate principles of justice from behind a 'veil of ignorance,' namely, from a position in which they are making decisions about how a society will function before they know who they will turn out to be in this society. For example, in the original position, agents do not know their social status, natural abilities, or conceptions of the good (Rawls, 1971: p. 12). Such agents, like Kantian agents, are not influenced by the particular desires and preferences that are contingent on being embedded in an actual situation. Because of this, their formulation of the principles of justice is taken to be the product of a 'pure' self, and hence genuinely self-originating.

The Kantian conception of autonomy has two aspects. First, autonomy is a function of a conception of morality that is encapsulated in the categorical imperative, or, in Rawls' account, in the principles of justice. The categorical imperative provides a standard according to which we can judge whether a particular example of reasoning is autonomous. If an agent's reasoning issues in the categorical imperative, then it is autonomous. Otherwise, it is not. (Thus, the Kantian account could be classified as both substantive and externalist.) Second, since autonomy manifests itself when the Kantian 'true' self is expressed through the formulation of the moral law, the Kantian account presupposes a metaphysical or 'noumenal' self. Both aspects of the Kantian view are contentious. Critics challenge the notion of a universally valid moral law as well as the concept of a metaphysically pure autonomous will. In addition, Rawls' account of the agent operating in the original position has been criticized as being unfaithful to empirical reality. Feminists and communitarians have argued that this agent is 'atomistic,' that is, existing in a vacuum divorced from the social relations in which actual agents are embedded (e.g., Sandel, 1982). No such agent exists, because agents are always the product of family influences, socialization, and so on. Moreover, an agent stripped of desires, interests, and preferences cannot engage in the imaginative moral reasoning required to formulate principles of justice. A further difficulty is that the Kantian conception is said to lead to an impoverished account of the value of autonomy. It is associated with the claim that autonomous agents are, and ought to be, substantively independent or self-sufficient, which in turn is associated with the character ideal of the 'self-made man.' Critics – especially feminists – have challenged this character ideal, and questioned whether substantive independence is really a value that a theory of autonomy, or normative theories in general, should promote. They have argued that a conception of autonomy should not exclude the possibility of agents having significant relationships of interdependency, such as those obtaining with family members (e.g., Friedman, 1997).

Procedural Theories of Autonomy

Theorists of autonomy have responded to the problems inherent in the traditional Kantian conception by offering compatibilist accounts, namely attempts to explicate autonomy within the network of physical and social forces in which agents operate. The notion of the self that is employed in procedural theories is empirical not metaphysical; procedural theories do not require that agents achieve substantive independence from the empirical conditions in which they are embedded. Rather, it is sufficient for autonomy that agents achieve procedural independence, that is, that their reasoning processes satisfy certain formal and procedural conditions. Procedural theories are both content-neutral and morally neutral. They are content-neutral because they do not require that the reasoning of autonomous agents delivers preferences or desires with particular moral contents. It is not required, for example, that the outcomes of autonomous reasoning correspond to what would be required by the universal moral law. Procedural theories are also morally neutral: they do not invoke background moral standards external to the agent as conditions of autonomy. It has been proposed that both content neutrality and moral neutrality are crucial aspects of a notion of autonomy that is useful in liberal political theory. It has been argued that only procedural conceptions of autonomy are compatible with liberalism (Christman, 2009).

The key task of procedural conceptions therefore is to distinguish when socialization undermines autonomy from when it does not. Procedural theorists argue that socialization may undermine autonomy by blocking either competency conditions or authenticity conditions. For example, John Christman defines agents as competent just in case they are capable of critical reflection and of forming 'effective' intentions (Christman, 2009: p. 154). If socialization undermines minimal capacities for critical reflection, or an agent's ability to form effective intentions, it also undermines autonomy. However, it is the authenticity condition that is taken by procedural theorists to be the 'core' of the notion of autonomy (Christman and Anderson, 2005: p. 3). In this section, I describe three conceptions of authenticity that have been offered by procedural theorists.

Endorsement or 'Identification'

The most influential procedural approaches are those of Gerald Dworkin and Harry Frankfurt (Dworkin, 1970; Dworkin, 1988; Frankfurt, 1971; Frankfurt, 1988). Both argue that what distinguishes autonomous from nonautonomous critical reflection is endorsement – agents' sense of engagement or 'identification' with their preferences or desires. In Frankfurt's terms, an autonomous will is the will the agent wants. Consider his distinction between a willing and an unwilling drug addict. The free will of both is hampered because addiction has undermined their 'freedom to do otherwise' (Frankfurt, 1971). However, the willing addict identifies with and endorses the desire for the drug, and hence has an important kind of freedom that the unwilling addict lacks. The unwilling addict is a mere 'passive bystander' with respect to the physiological addiction, whereas the willing addict has made the desire for the drug his own by identifying with it.

On Frankfurt's account, freedom of the will is spelled out using a hierarchy of desires. A first-order desire is autonomous just in case it is endorsed by a second-order volition, namely, a second-order desire that the first-order desire be effective (Frankfurt, 1971). His account therefore analyzes free will using conditions that an agent's present motivational state must satisfy. Alternative approaches introduce conditions that allow historical reflection on the processes of development of the motivational state. For example, Gerald Dworkin's analysis is hierarchical yet historical: autonomy is "a second-order capacity of persons to reflect critically on their first-order preferences, desires, wishes and so forth and the capacity to accept or attempt to change these in the light of higher-order preferences and values" (Dworkin, 1988: p. 20). A capacity allows reflection on the processes by means of which an agent acquires desires and preferences. It also distinguishes between an agent's autonomy on the one hand, and a particular exercise of autonomy on the other.

Important objections have been raised to endorsement accounts. The first focuses on their hierarchical nature. Even if first-order desires are endorsed by second-order volitions, this is not sufficient to ensure autonomy unless the second-order volitions themselves are endorsed. It has been argued that the problem results in a regress unless we introduce a qualitative distinction among levels, for example, between higher order values and first-order desires (Watson, 1975). However, the regress objection can be generalized to many hierarchical accounts, because whatever the nature of the higher order level, it can always be questioned whether it truly represents free agency. The higher order level itself will always be the outcome of the social forces influencing an agent. A second objection is that the endorsement condition may be too stringent, because it seems that certain unendorsed desires should count as autonomous. Suppose that, out of habit, an agent goes on vacation to the same destination every year. The fact that the agent fails to attend critically to the desire and does not endorse it each time should not rule out its being autonomous. Third, it has been suggested that the endorsement condition is too weak. Frankfurt's version of the endorsement account relies on the idea that, although an unwilling addict seems to intentionally inject himself with heroin, he prefers not to, and hence he does not endorse the desire to inject himself. It has been argued that (all things considered) intending to do something and preferring to do something are indistinguishable, and thus if agents intend to do something, they also prefer to do it, and to endorse it. Therefore, insofar as unwilling addicts intend to inject themselves with the drug, they also endorse it. The objection claims that endorsement merely distinguishes intentional from nonintentional agency, and not autonomous from nonautonomous agency. The apparent lack of autonomy of the unwilling addict is therefore not due to a lack of endorsement (Buss, 1994).

Authenticity as Historical Nonalienation

In early work, John Christman proposed a counterfactual and historical criterion of autonomy: agents are autonomous with respect to a certain preference or desire only if they do not resist its development when attending to the process of its development, or would not have resisted had they attended to the process (Christman, 1990, 1991). In response, it was pointed out that agents might repudiate the way in which a preference or desire was formed; an agent might, for example, repudiate an extremely doctrinaire religious upbringing, yet nevertheless be autonomous with respect to the religious values that were formed as a result of this process (Mele, 1995: pp. 138–139). In recent work, Christman formulates a modified 'hypothetical reflection condition' to spell out the notion of authenticity required for autonomy. A preference or desire is authentic and hence autonomous, if, were the agent to reflect critically on the historical processes leading to the formation of the desire, he or she would not be alienated from the desire (Christman, 2009: pp. 155–156). Alienation is a "combination of judgment and affective reaction. To be alienated is to feel negative affect, to feel repudiation and resistance…to feel a need to repudiate that desire or trait, to reject it and alter it as much as possible and to resist its effects" (Christman, 2009: p. 144). If one is (or would be) alienated from a desire but does not succeed in repudiating it, one is inauthentic and heteronomous with respect to the desire. Hence, on Christman's account, autonomy is compatible with preferences being habitually or even unconsciously formed, or being formed through processes that the agent on reflection would resist.

However, even this historical criterion is difficult to maintain in the face of apparent counterexamples. Consider Thomas Hill's example of the Deferential Wife: "She buys the clothes he

prefers, invites the guests he wants to entertain, and makes love whenever he is in the mood. She willingly moves to a new city in order for him to have a more attractive job… she tends not to form her own interests, values, and ideals, and when she does, she counts them as less important than her husband's" (Hill, 1991: p. 5). One would think that such excessive deference would be incompatible with autonomy, but the historical criterion cannot adequately explain why. The very fact that gender norms that treat women's submissiveness as desirable are so effectively internalized makes it unlikely that the agent would experience negative affect or alienation when reflecting on the genesis of the norms that she has endorsed (cf Benson, 1991). Christman's historical condition therefore does not account for cases that are often thought to be paradigms of inauthentic and nonautonomous preference formation.

Self-Discovery

Diana Tietjens Meyers describes acting autonomously as "the difference between doing what one wants and doing what one really wants. The autonomous self is not identical with the apparent self; it is an authentic or 'true' self" (Meyers, 1987: p. 619). For Meyers, the authentic self emerges when a person exercises the 'agentic skills' that characterize autonomous people. She writes that "autonomous people exercise a repertoire of skills to engage in self-discovery, self-definition and self-direction, … the authentic self is the evolving collocation [sic] of attributes that emerges in this ongoing process of reflection, deliberation and action" (Meyers, 2005: p. 49). These include skills of introspection, imagination, communication, and memory (Meyers, 2002: p. 20). Hence, Meyers does not propose that competency conditions and authenticity conditions of autonomy should be distinguished, but rather that the ongoing exercise of what she terms 'autonomy-competency' delivers a true or authentic self. Marilyn Friedman argues that being autonomous requires 'self-reflective affirmation' with respect to one's preferences and values. Through the process of critical affirmation (and reaffirmation), preferences and values become a person's own: "When someone reflectively reaffirms wants and values that are important to her…they become part of the perspective that defines her as the particular person she is. They embody the 'nomos' of her self…" (Friedman, 2003: p. 6). Friedman adds that the process of self-reflective affirmation "must be relatively unimpeded by conditions, such as coercion, deception and manipulation" (Friedman, 2003: p. 14).

One important focus in the work of both Meyers and Friedman is the question of whether autonomy is compatible with conditions of oppression including situations in which women themselves appear to be committed to oppressive gender norms. Meyers argues that "patriarchal noise can overwhelm women's voices and choices," but that autonomy skills "endow women with the capacity to fashion self-portraits and self-narratives in their own voices and to lead their own lives" (2002: p. 32). She points out that the development of the specific skills required for autonomy competency, such as introspection and imagination, can be impeded by oppressive practices and cultural stereotypes. It is important therefore that adequate education be available, especially to young girls, to allow children to develop autonomy skills. Friedman considers the impact of familial and community relationships on the skills of critical reflection required for autonomy (Friedman, 2003: p. 97). She notes that restrictive or oppressive social relationships may hamper an agent's ability for autonomy, or they may provide role models, self-trust, self-confidence, and so forth, which enhance the capacity (Friedman, 2003: p. 97).

For Meyers and Friedman, and on procedural accounts in general, there is no reason in principle why choosing subservience, or adopting norms that are oppressive, could not be autonomous. Critics have responded that preferences for one's own subordination are irrational and impair autonomy because they are inconsistent with the agent having an appropriate sense of his or her own moral worth (Superson, 2005). Others have suggested that severely constraining external circumstances, including the lack of a sufficient number of adequate options, compromise agents' freedom and autonomy, and hence procedural accounts that employ only psychological conditions in their analysis of autonomy are unsatisfactory (e.g., Raz, 1986; Brison, 2000; Oshana, 2006).

Neo-Kantian Theories

Procedural accounts usually assume that the conditions they identify, which are a function of actual or historical critical reflection, are both necessary and sufficient for autonomy. What could be called 'neo-Kantian' conceptions introduce additional external, moral conditions: autonomy requires that agents have a capacity or competency to identify and apply relevant norms. Since the norms are external moral or interpersonal norms, this competency is in part defined using external moral or interpersonal conditions. Hence, although certain procedural criteria such as a minimal capacity for critical reflection may be necessary for autonomy, they are not sufficient.

Susan Wolf adopts a normative competence view in which the capacity that is essential for autonomy is the capacity to track objective moral reasons. Wolf considers agents who have experienced morally impoverished or distorting socialization. For instance, suppose that JoJo is the son of an evil and sadistic tyrant who has been raised to respect his father's values and emulate his desires, so that he thoroughly embraces his father's worldview. Suppose that on procedural theories, JoJo counts as autonomous; he holds these values and desires as a result of appropriate self-reflection and therefore is governed by what he really wants. Wolf proposes that he is neither free nor morally responsible because his upbringing has undermined his capacity to distinguish right from wrong: "[i]t is unclear whether anyone with a childhood such as his could have developed into anything but the twisted and perverse sort of person that he has become" (Wolf, 1987: p. 54). On Wolf's account, the failure of autonomy is a failure of a capacity to track an objective aspect of the world, namely, 'the moral' or 'the right.' Since for Wolf the demands of morality are equivalent to the demands of objective 'reason,' in order to be autonomous, agents must be capable of discerning the requirements of reason.

Benson employs a parallel notion of normative competence, though it does not require a capacity to track objective

morality, but rather an ability to identify and deploy norms that are appropriate to a particular domain (Benson, 1987: p. 486). He writes that: "[F]ree agency requires normative competence, an array of abilities to be aware of applicable normative standards, to appreciate those standards, and to bring them competently to bear in one's evaluations of open courses of action…" (Benson, 1990: p. 54). Benson points out that normative competence does not require that the content of agents' preferences correspond to the content of the applicable norms because the exercise of a capacity in particular cases could fall short. In particular cases "normatively competent persons can choose what is unreasonable or wrong or value what is bad" (Benson, 2005: pp. 133–134). Hence, normative competence views do not conflate autonomy or self-rule with 'right-rule.'

There are nevertheless controversial issues raised by normative competence accounts. The first is that of the status of the moral and other norms that are employed to explicate normative competence. Wolf's account is controversial because it relies on objective reason. Benson's normative standpoints are intersubjective standpoints. Nevertheless, it is questionable whether competently deploying such standards is a plausible mark of autonomy. Intersubjective norms can be erroneously applied to agents, in particular in circumstances of oppression. Agents who recognize such norms and treat them as reasons for choice and action may be less autonomous than those who reject outright the applicability of intersubjective and oppressive norms that are applied to them. Finally, normative competence accounts may seem to collapse the distinction between responsibility and autonomy (Benson, 1994: p. 665). In the case of JoJo, for example, although it is plausible that the comprehensiveness of his socialization absolves him from full moral responsibility for his acts, it may be too quick to conclude that his acts are not the product of his own (autonomous) agency.

Self-Regarding Attitudes and Dialogical Approaches

Approaches that employ self-regarding attitudes propose that although critical reflection may be necessary for autonomy, it is not sufficient (Govier, 1993; McLeod, 2002; Benson, 1994). They claim that certain emotional states and attitudes to oneself, such as self-trust, self-esteem, and self-respect, are additional necessary conditions. Paul Benson describes a case of a woman with a certain personality type who is treated as pathological and crazy by her husband and the medical establishment (Benson, 1994: pp. 555–557). The woman's response is helplessness and disorientation leading to a loss of self-worth. Moreover, the woman does not resist the process through which she loses her self-worth because "she arrives at her sense of incompetence and estrangement…on the basis of reasons that are valued by a scientific establishment which is socially validated and which she trusts" (Benson, 1994: p. 657). Benson argues that, although the woman's critical reasoning faculties are intact, she nevertheless lacks autonomy because of a diminished sense of self-worth.

Theorists employing self-regarding attitudes notice that these attitudes can be undermined or enhanced by interpersonal conditions. Thus, self-regarding attitudes are often dialogical. On Benson's approach, self-worth is in part a requirement of "regarding oneself as being competent to answer [to others] for one's conduct" (Benson, 1994: p. 660). He develops this idea in later work to argue that autonomous agents are those who treat themselves as answerable for their conduct, who claim the authority to speak for themselves (Benson, 2005: p. 111 ff.). Others have also proposed that answerability is a key condition of autonomy (Anderson and Honneth, 2005; Mackenzie, 2008; Westlund, 2009). For example, Andrea Westlund argues that autonomy is neither a structural nor a historical capacity of critical reflection, but rather a disposition to treat oneself as answerable to the critical demands of others (Westlund, 2009: p. 35).

Both types of account potentially suffer from the objection that the conditions they identify are not sufficient for autonomous agency. Suppose an agent acquiesces in and endorses a set of circumstances or an ideology that is oppressive to her. In one sense, she may lack a sense of self-worth, but she may also regard herself as competent to answer for her actions in terms of those norms. Indeed, many agents who seem to be paradigms of nonautonomy, such as the Deferential Wife described in 'Authenticity as Historical Nonalienation,' will have the self-trust and self-esteem required to articulate their commitment to the norms they embrace. Indeed, the more deeply committed the agent is to such norms, the more likely it is that he or she will treat himself or herself as answerable for them. Thus, it seems that answerability could be present in many cases in which autonomy is not.

External Moral and Social Conditions

The theories of autonomy surveyed so far have treated autonomy as a psychological feature of agents, although in some cases we saw that the defining conditions of the psychological features include historical or other external conditions. Procedural theories require psychological processes of critical reflection. Normative competence theories rely on the agent's psychological capacity to discern substantive norms that are intersubjective or objective and hence are external to the agent. Dialogical approaches invoke agents' psychological states, such as sense of one's own answerability, although they analyze these states as related to external interpersonal conditions. In contrast to these accounts, which define autonomy primarily in psychological terms, the set of theories described in this section claim that agents with fully functioning, healthy psychologies could nevertheless have their autonomy undermined by external conditions.

Joseph Raz proposes that autonomy requires having morally adequate options in addition to mental ability, and independence from coercion and manipulation by other agents (Raz, 1986: p. 369). Consider a woman on a desert island who is hounded by a wild animal and has to spend all her time and energy planning for survival. The woman has a variety of options in addition to the mental abilities necessary for planning but the options she has are inadequate. For one thing, they are "dominated by her one overpowering need and desire to escape being devoured by the beast" (Raz, 1986: pp. 374–376). For another, having 'adequate options' is understood by Raz as

a moral requirement: "[a]utonomy requires that many morally acceptable options be available to a person" (Raz, 1986: p. 378).

Marina Oshana also claims that autonomy can be undermined by conditions in the world that do not necessarily affect the agent's psychology. She argues that agents who are reflective and psychologically competent can have their autonomy undermined by finding themselves in – or deliberately adopting – a situation in which their 'practical control' is removed: "We correctly attribute autonomy to a person when the person has *de facto* power and authority to direct affairs of elemental importance to her life within a framework of rules (or values, principles, beliefs, pro-attitudes) that she has set for herself" (Oshana, 2007: p. 411). For Oshana, agents living under conditions of severe social constraint, such as those obtaining under slavery, have limited autonomy. Such 'sociorelational' external conditions interfere with autonomy conceived as a temporally extended, 'global' condition of agents; they remove the *de facto* power that is required for autonomy on Oshana's account.

It has been suggested that sociorelational views are objectionable because they permit paternalism or are implicitly committed to an egalitarian ideal and hence a kind of perfectionism (Holroyd, 2009; Christman, 2004, 2009). It has also been alleged that these accounts are too quick to claim that severely constraining or morally inadequate external conditions always undermine autonomy. Rare individuals, such as Rosa Parks and Martin Luther King, despite being subject to constraining and morally objectionable conditions, resist oppression and in so doing seem to manifest autonomy (Noggle, 2011). If this is right, external sociorelational conditions that seem to impede agents' practical control do not *ipso facto* undermine autonomy.

Avant-Garde Art and Artists

Abstract

The concept of the avant-garde has been applied to three types of changes in the arts: in the aesthetic content of art, in the social content of art, and in the norms surrounding the production and distribution of artworks. First used in France in the 1830s, the term acquired new meanings and connotations in the twentieth century, ranging from aesthetic innovation to alienation. The best-known literary and philosophical theories of the avant-garde have concentrated on the content of avant-garde works, while sociological theories and research have been concerned with the production and reception of these works. In the context of postmodernism at the end of the twentieth century, alternatives to the aesthetic and social values of art establishments are less likely to come from avant-gardes than from artists outside the system. The visual strategies and tactics of artistic avant-gardes of the prewar period have been appropriated by the electronic media and other forms of popular culture such as advertising, fashion design, and music videos. Works created for popular consumption that use avant-garde techniques are unlikely to contain critical content. As high culture has become less distinct from popular culture, the concept of the avant-garde has lost many of its former connotations. The avant-garde's mission as iconoclast and social rebel has been taken over by cultural avant-gardes in the form of a wide variety of micropolitical movements.

Since the concept of the avant-garde appeared at the beginning of the nineteenth century, it has been applied to a wide variety of aesthetic and social practices. Analysis of different uses of the term shows that it has been applied to three types of changes: in the aesthetic content of art, in the social content of art, and in the norms surrounding the production and distribution of artworks (Crane, 1987: pp. 14–15). For example, the term avant-garde is applied to the aesthetic content of art objects: (1) when those works represent a redefinition of conventions for creating art, often in such a way that they are perceived as violating taboos and as shocking or offensive; (2) when they involve the use of new tools and techniques, or concern the nature or use of techniques per se; and (3) when they redefine what can be considered an artwork. The term is applied to the social content of artworks when they express social or political values that are critical of or different from the dominant culture, when they attack art institutions, and when they attempt to redefine the boundaries between high and popular culture. Finally, the term is applied to creators of artworks when they attempt to alter the social context for the production of art (e.g., appropriate role models, critics, and publics for artists), the organizational context in which art is displayed and distributed, and the social role of the artist in terms of his or her participation in other social institutions, such as education, religion, and politics. This article examines the evolution of artistic avant-gardes since the nineteenth century, theories of the avant-garde, and sociological research on the social organization and reception of avant-gardes.

Origins and Evolution of the Term

Originally referring to a section of an army that marched ahead of the troops, the term avant-garde was first used in France in the 1830s to refer to artists as leaders and creators of a new social order (Nochlin, 1968: p. 5). Until the middle of the nineteenth century, the term generally meant that an artist was both politically and aesthetically progressive. The artist was expected to lead society in new directions and to be in conflict with tradition and the establishment. Subsequently, the term began to refer to artists whose works expressed alienation from bourgeois society in the form of ironic or destructive commentaries on social and artistic values rather than commitment to specific programs for social or aesthetic change. These different elements associated with avant-gardes – political rebellion, aesthetic rebellion, and alienation – continued to be important in the twentieth century.

At the beginning of the twentieth century, the idea of the avant-garde as alienation was given a new dimension by Marcel Duchamp who created artworks or 'ready-mades' by making minor changes in existing artworks or by arbitrarily declaring that commonplace objects, such as a mass-produced urinal, were artworks. This conception of the avant-garde became the basis for the Dadaist movement consisting of groups of artists, located in several European cities and in New York, whose members attempted to destroy artistic conventions and to shock the public. In this period, the Dadaists shared with the Italian Futurists (whose aesthetic innovations were very different) "a belief that they were ahead of the society in which they lived and that they were breaking social bonds of restraint" (Taylor, 1968: p. 97). This attitude led the Futurists to engage in flag burnings and to stage assaults on theaters and opera houses, although they were not actually interested in changing the social order but in aesthetic change and in "continuous revolution as a way of art" (p. 100).

During the twentieth century, the term was applied to groups of artists who developed new aesthetic programs, many of them concerned with problems of visual perception and the interpretation of visual experience. This type of art dealt with aesthetic and technical issues and was detached from the concerns of everyday life. Although the term avant-garde appeared before the development of modernism in the arts, there was a pronounced affinity between avant-gardes and modernism, which was reflected in the modernist's

commitment to the development of a particular style. At the end of the 1930s, Clement Greenberg, an American art critic, provided a theoretical justification for the type of avant-garde that has proven to be most characteristic of the second half of the twentieth century, one which engages in art for art's sake and which is concerned with aesthetic values rather than with social conflict or political struggle (Orton and Pollock, 1981: p. 322). Another American art critic, Harold Rosenberg (1968), argues that the suppression of avant-garde art by the Communists and later by the Nazis marked the beginning of the separation of political and artistic avant-gardes. As an example of this rupture during the postwar period, he cites the 1968 Venice Biennale where militant students denounced the artworks as 'art for dealers and the rich.'

In the late twentieth century, the success of Pop Art, Conceptual art, and neo-Expressionism signaled both the triumph of the ironic, alienated conception of the avant-garde and a decline in the priority attached to aesthetic innovation, reflecting the increasing influence of postmodernism in all forms of culture. Unlike the modernist, the postmodernist is not interested in style conceived as a consistent, integrated set of aesthetic elements or in using a style to express opposition to the dominant culture. Instead, the postmodernist engages in *pastiche*, bringing together disparate elements from many previous texts, regardless of whether they produce a coherent unity. According to Goldman (1992: p. 214), the meaning of postmodernist texts cannot generally be discerned from analyzing the texts themselves but only by asking where the elements in the text come from. Postmodernist works tend to expose or reinterpret rather than criticize or attack the dominant culture.

The relevance of the concept of the avant-garde was confirmed in the 1990s by the intensity of controversies surrounding government funding for artworks that challenged conventional attitudes and values. The allocation of funds by the United States government agency, the National Endowment for the Arts, to support exhibitions of artists such as Robert Mapplethorpe and André Serrano, whose works were perceived as having transgressed moral and religious boundaries, created enormous opposition and even pressure to dissolve the agency itself. However, it is significant that these artists were not members of art movements and that their activities did not engender such movements. Some authors claim that the avant-garde is dead and that contemporary artists do not correspond to this concept. Dunn (1991: p. 124) argues that, in the highly fragmented and ambiguous context of postmodern culture, artistic avant-gardes have been replaced by cultural avant-gardes to which the term avant-garde is seldom applied. These movements engage in collective protest and challenge tradition and hegemonic structures on a wide range of social and cultural issues such as class, gender, sexuality, race, peace, and ecology.

Theories of the Avant-Garde

Theorists who have written about the avant-garde have generally based their analyses on certain types of avant-gardes, particularly those that have rebelled against the dominant culture and excluded others from consideration. A major strand of theory concerning the avant-garde derives from the critical theorists, known as the Frankfurt School. Adorno despised popular culture produced by culture industries on the grounds that it provided shallow entertainment that distracted and manipulated the unsophisticated public. He interpreted the role of high culture and its avant-gardes as that of challenging dominant institutions and conventional ways of thought. For Benjamin (1968), the significance of Dadaism as an avant-garde was that the Dadaists deliberately attempted to produce artworks that lacked an aura of uniqueness and authenticity, thus undermining the status of the arts as sacred.

Two leading theorists of the avant-garde are Bürger (1984) and Poggioli (1968). A contemporary critical theorist, Bürger examines the activities of avant-gardes and the social content of their work, arguing that what is most characteristic of avant-gardes is their challenge to art institutions. Instead of creating works of art that were autonomous, complete, and separate from social life, the avant-garde attempted to create works that challenged the public to make sense of them and to relate them to their daily lives. On this basis, he restricts the title of avant-garde to a small number of movements, including Dadaism, early Surrealism, and some aspects of Futurism.

Poggioli (1968) argues that the dominant characteristic of avant-garde art is alienation in all its forms – psychological, social, economic, historical, aesthetic, and stylistic. Bourgeois, capitalist, and technological society provides avant-garde artists with freedom to create while the tensions underlying this type of society provide them with 'a reason for existing.' In Poggioli's view, the avant-garde artist is motivated by nostalgia for an earlier period when the artist was treated as a creator rather than as a parasite and a producer.

Recent debates about the contribution of artistic avant-gardes to politics in the postwar period also suggest that avant-garde artists in the 1960s perceived themselves as having broader social and political roles than those that are ascribed to artists today. Rasmussen (2009) analyzes three art movements of the 1960s – the Situationist International, the Artist Placement Group, and the Art Workers' Coalition – all of which attempted to use avant-garde art as a political tool to address social issues and bring about social change.

Huston (1992) is critical of these theories on the grounds that they are unable to explain and often do not even consider factors affecting the production and social reception of avant-garde arts. He argues that most styles of avant-garde art ultimately succeed in winning the support of the art establishment, which initially rejected them but that theories of the avant-garde are not helpful in explaining these developments. In his view, these theories tend to legitimate avant-garde art as *true* art and "a certain vision of the artist as a great artist" (p. 78). In other words, he sees the concept of the avant-garde as an ideological category that accepts uncritically artists' conceptions of their situation and tends to be used in such a way as to legitimate certain types of art rather than others (p. 79).

These theories of the avant-garde can also be faulted on the grounds that they treat the distinction between high culture and popular culture as unproblematic and view high culture and its avant-gardes as being the most influential and prestigious forms of culture. In fact, the enormous proliferation of different forms of popular culture (film, television, and popular music) has made it difficult to ignore the aesthetic

influence of these cultures on traditional arts and in everyday life, and has, at the same time, decreased the influence of the traditional arts such as painting, theater, dance, poetry, and experimental music. The latter tend to be appreciated by distinct and relatively small subgroups within the middle and upper classes, generally located in a few major cities.

Bauman (1997: p. 95) argues that avant-gardes have disappeared in this postmodern context because there is no longer any clear-cut distinction between styles that can be considered more or less advanced or more or less progressive than others. Instead, while there is a great deal of change in contemporary arts, these changes are 'random, dispersed, and devoid of clear-cut direction.' The importance of an artwork is determined less by aesthetic elements than by publicity and the notoriety that results from it. Several factors, such as the enormous increase in the prices of works by successful artists as well as in demand for these works, have contributed to a situation where successful artists have more to gain from creating artistic brands, making their work instantly recognizable to art collectors and dealers, than from creating works that critique the status quo or that are difficult to understand (Lury, 2005).

Sociological Studies of Avant-Gardes

While theorists of the avant-garde such as Bürger and Poggioli emphasize the aesthetic, political, and ideological programs of avant-gardes, sociological research has focused on (1) the relationships among artists and (2) the reception of artworks by art institutions and by the public. The dominant view underlying recent studies in the sociology of art is that the significance of all types of art is socially constructed. The question becomes one of identifying the social processes through which this takes place. A major concept is that of the art world, in which art is produced through the efforts of artists in collaboration with members of many other occupations (Becker, 1982).

White and White (1965) document changes in social and institutional structures that supported the activities of artists in nineteenth-century Paris. These changes facilitated the emergence of avant-garde styles. Specifically, the transition from academic art to Impressionism, a style that transformed the aesthetic conventions of the period, necessitated the development of a new occupation for buying and selling paintings, that of the art dealer, and the appearance of a new type of collector, drawn from the expanding middle class.

Becker (1982: pp. 304–305) does not use the term avant-garde, preferring to use the concept of 'artistic revolution.' The latter is set in motion by ideological and organizational activities among art world participants. Ideological changes are revealed by the appearance of 'manifestos, critical essays, aesthetic and philosophical reformulations, and revisionist histories,' while organizational changes lead to shifts in control over 'sources of support, audiences, and distribution facilities.' Like White and White, Becker argues that the most important factor affecting the success of revolutions is the extent to which their proponents are able to take over the art world's organizational structure and facilities. He says (p. 310): "Ideas and visions are important, but their success and permanence rest on organization, not on their intrinsic worth."

Crane (1987: pp. 137–143) traces changes in the roles of artistic avant-gardes during the twentieth century and particularly in the decades after World War II. She identifies three artistic roles that existed in the prewar period, that of the aesthetic innovator who analyzed visual reality in terms of its constituents such as color and form, the iconoclast, who attacked bourgeois conventions and art institutions, and the social rebel whose target was political and economic institutions. In the postwar period, these three roles were gradually transformed. The role of the aesthetic innovator emerged as the dominant role but in response to the expansion of public, private, and corporate expenditures and the creation of new cultural institutions, these artists are increasingly identified with the middle class in terms of lifestyle and the content of their works. Iconoclasts thrived during the 1960s but after that decade concentrated upon exploring the limits of art itself or eliminating the boundaries between the arts and the media. Artists who moved in the latter direction came to see themselves as entertainers rather than members of an alienated avant-garde. There was little support for the role of social rebel. Political art and a humanistically oriented representational art remained on the periphery of the art world. The role of social rebel was replaced by the democratic artist who communicated social and aesthetic ideas to audiences in poor urban neighborhoods and who had virtually no contact with the art world (for an examination of art avant-gardes in Israel see Greenfeld, 1988).

At the end of the twentieth century, in the absence of strong avant-garde movements within the art world, alternatives to the aesthetic and social values of the art establishment often came from outside the system, specifically from the works of untrained and often uneducated artists, including folk and ethnic artists, the homeless, prison inmates, elderly people in nursing homes, and hospice patients (Zolberg and Cherbo, 1997: p. 1). The so-called outsider artists who worked alone and who had formerly been completely ignored by the art establishment were now supported by a network of dealers, curators, and collectors.

Drawing on poststructuralist theories, sociologists view the meaning of an artwork as being constructed in the process of reception as much as in the process of creation. The response of the audience constitutes part of the meaning of the artwork. Consequently, the meaning of an avant-garde movement changes in different social contexts as different social groups with particular institutional interests engage in 'a struggle over the text.' Using this perspective, Halley (1985) examined the reception of the Dada movement and showed that, in its own time, its importance was not recognized. Audiences were very small and the movement was overshadowed by Surrealism. Subsequently, different social groups such as art historians, curators, critics, and artists themselves developed competing and conflicting interpretations of Dada and often misunderstood or ignored the original intentions of Dadaist works. From the beginning, there was more interest in Dada in the United States than in Europe, which helps to explain its influence on American avant-garde groups in music, dance, and art in the postwar period. These groups incorporated Dadaist ideas into their own artworks, contributing to wider recognition of the movement.

Bourdieu's (1984) theory argues that support for art movements is associated with social class but that a specific

aesthetic statement will appeal to different social strata, depending on its significance in the definition of taste in different time periods. The social positions of supporters of an emerging avant-garde movement differ from the social positions of those that admire the movement after it has received recognition. For Bourdieu, the important aspect of the avant-garde is not its aesthetic characteristics but its structural position in the art world, which is subject to change over time.

Attempts to show the relationship between social class and support for artworks that have been considered avant-garde in the past, such as abstract art, have yielded ambiguous results (Halle, 1992). However, appreciation of artworks that are still considered avant-garde is confined to relatively small groups even within the middle and upper classes, as is suggested by the intensity of the conflicts that arise when such works are displayed in public places (Heinich, 1997).

At the present time, the concept of the avant-garde is most meaningful in countries outside Europe and the United States, such as Japan, and particularly in developing countries, such as China and Latin America. Recent studies include (1) an ethnographic study, which attempts to interrogate the notion of the avant-garde in Japan through an analysis of avant-garde music and its audience in Japan (Plourde, 2010); (2) case studies of artists and art worlds in Beijing, which reveal an evolution, not unlike what has taken place in the West, away from avant-garde underground movements toward the development of a profitable, entrepreneurial art market in which market forces define the content of art (Tang, 2009); and (3) an analysis of changes in the types of discourse adopted in the literary works by a group of Mexican avant-garde writers (Parodi, 2006).

Avant-Gardes and Popular Culture

In the past two decades, the electronic media have appropriated most of the visual strategies and tactics of artistic avant-gardes from the prewar period. Caldwell (1995: p. 8) claims that "every framework of the avant-garde … had become highly visible in some form in the corporate world of the new television." Kaplan (1987: p. 55), in an attempt to classify music videos in the mid-1980s, found that all the categories she identified used avant-garde strategies. The originators of punk music used many of the tactics identified with early twentieth-century avant-gardes, such as the blurring of boundaries between art and everyday life, intentional provocation of the audience, and disorganization of accepted styles and procedures of performance (Henry, 1984).

Recent studies have examined avant-gardes in popular music (Lena and Peterson, 2008; Lena, 2012), jazz (Currie, 2010; Krnic, 2010), fashion design (Mears, 2008; Kawamura, 2004), culinary innovation (Hollows and Jones, 2010; Cunningham, 2008), and video games (Kirkland, 2010). These studies show the importance of the concept in understanding the emergence and development of these forms of culture. Use of the term increases the legitimacy of these types of culture.

In their analysis of types and trajectories of music genres (which they define as "systems of orientations, expectations, and conventions that bind together an industry, performers, critics and fans in making what they identify as a distinctive sort of music"), Lena and Peterson (2008: p. 698) identify four types of genres, one of which they labeled 'avant-garde.' Avant-gardes in popular music "engage in experimental practices, including playing standard instruments in unconventional ways, creating new musical instruments, and modifying objects that have not previously been used in the production of music" (p. 703). Two-thirds of new forms of music that appeared in the United States during the twentieth century originated as avant-garde genres.

The term, avant-garde, performs an important role in the long-term controversy over whether jazz is a form of high or popular culture (Krnic, 2010). Currie (2010) treats jazz improvisation as an avant-garde and attempts to understand the formation of subcultural communities surrounding this type of music.

Avant-garde practices are often used by emerging fashion designers to attract attention to their collections. Several, very influential Japanese designers have frequently been labeled avant-garde (Kawamura, 2004; Mears, 2008). Their work has been recognized in many museum exhibitions. The Italian fashion house, Prada, has benefited from its patronage of avant-garde artists and architects, which included gallery ownership, contemporary art collecting, and commissioning architects to design its stores. The company's connection with these artists and architects enhanced its symbolic capital and the distinctiveness of the brand (Ryan, 2007).

Recently, the term, avant-garde, has begun to be applied to culinary innovation. Hollows and Jones (2010) show that an emphasis on avant-garde innovation and experimentation is being used by chefs in high-end restaurants to increase their profits. In one case, a series of television shows in which a British chef demonstrated his intellectual and aesthetic practices had the effect of securing for him the label of 'culinary alchemist.'

Finally, an analysis of a survival horror video game series, Silent Hill, argues that the series qualifies as an art form on the basis that its texts exhibit formal devices used by art cinema, such as 'realism, ambiguity, psychological complexity, and self-reflexivity,' that its advertising emphasizes these qualities rather than gaming, and that its production has been the subject of a documentary (Kirkland, 2010).

However, assimilation by the mass media of oppositional stylistic devices associated with avant-gardes raises the question of the extent to which oppositional themes are being disseminated. High-culture institutions frame oppositional messages in such a way as to highlight their effect: an entire evening at the theater devoted to a particular playwright, an entire gallery or museum wing devoted to the work of a particular artist for several weeks. By contrast, the sheer volume of messages of all kinds being transmitted by the mass media tends to obliterate the effect of oppositional messages when they do appear. Kaplan (1987: p. 65) points out that oppositional messages are likely to be 'overridden by the plethora of surrounding texts.'

The commitment of popular culture creators to the tenets of the avant-garde may be questionable. Bourdieu (1993) differentiates between high culture and popular culture using the concept of the cultural field. Esoteric works are created in cultural fields in which autonomous creators have substantial control over standards for content and economic criteria for success are less important than aesthetic criteria. Popular works

are created in cultural fields in which creators are subject to the demands of managers and entrepreneurs who control the distribution of these forms of culture. Economic interests predominate.

When fashion designers incorporate avant-garde devices in luxury clothing for wealthy clienteles, does this activity represent a genuine avant-garde or is it simply a marketing strategy to attract attention, either to the clothes or to products licensed under their names? (Crane, 2000). Using Bourdieu's theory of cultural fields, the luxury fashion market could be classified as belonging to what he calls the field of 'restricted production,' where commercial interests are subordinate to aesthetic considerations (Bourdieu, 1993; Bourdieu and Delsaut, 1975). This interpretation is plausible in relation to relatively small companies operating in a single location. It becomes more difficult to defend in relation to large fashion firms with clienteles over the world.

Benetton, an Italian clothing manufacturer, has commissioned advertisements in which photographs, often reprinted from the press, graphically portray social and political crises and calamities in order to increase public awareness of social, political, and environmental issues (Guerrin, 1998). However, critics have not accepted this advertising strategy at face value but have claimed that the company is exploiting tragic situations as a means of publicizing its products.

The ambiguity that emerges when an avant-garde creator associates with a commercial enterprise is seen in the outcome of the collaboration between Rem Koolhaas and Prada (Ryan, 2007). The avant-garde architect was selected to design several avant-garde stores for the company because his status of being on the 'cutting edge' was considered desirable for the company's image. The stores he created have dual functions, as art centers and as shops, but may be incomprehensible to many customers who lack the appropriate cultural capital. Koolhaas himself denounced the Prada project in print as an example of 'junkspace' in which all public spaces have been turned into shopping centers. He was in turn accused by critics of appropriating high culture for commercial ends.

Curiously, as some of the properties of high culture are being assimilated or co-opted by certain forms of popular culture, the old hierarchy of high and low is reappearing in the latter. For example, in popular music, certain genres are deemed superior to others and some artists' works are considered 'classics' in comparison with all the rest (Regev, 1994).

The Contemporary Relevance of Avant-Gardes

An analysis of the evolution of avant-gardes in art history, as well as a review of theories of the avant-garde and of relevant sociological research, suggests that the concept of the avant-garde applies to the behavior and activities of artists during a period of about 150 years. At the present time the term is being less frequently used because it is more difficult to identify avant-gardes in an era when diverse and fragmented post-modernist styles predominate. Ironically, the term now tends to be applied to works created for popular consumption that incorporate techniques but not ideological content from avant-garde movements that existed earlier in the century. Meanwhile, the avant-garde artist's mission as iconoclast and social rebel has been assumed by a broad range of 'micropolitical' movements outside the arts.

Avoidance and Approach Motivation: A Brief History

Abstract

The study of motivation has been of interest to researchers in all fields who are interested in examining the underlying causes of behavior. Approach and avoidance motivation, in particular, has been a topic of much discussion since the inception of the field of psychology. This article begins with a brief definition of the approach–avoidance distinction and covers the history of the construct. It continues with a conceptual discussion of the approach–avoidance distinction followed by a comparison of the varied terminology researchers have used to discuss this issue.

Introduction

The study of motivation has been a topic of interest for scientific researchers since the inception of the field of psychology. Since it can be applied to a variety of types of research in different fields, it is important to have a clearly defined and articulated conceptualization of the fundamental approach–avoidance distinction. This article begins by explaining relevant terms, then covers the history of the approach–avoidance distinction followed by a conceptual overview of approach and avoidance motivation and a discussion of terminological considerations (for additional details, see Elliot, 1999, 2008; Elliot and Covington, 2001, from which the present article draws heavily).

Definitions

Before delving into the history and conceptualization of approach and avoidance motivation, it is important to provide clear definitions of the terminology to be used in this article. 'Motivation' refers to the energization and direction of behavior (Elliot and Covington, 2001). 'Approach motivation' is used to describe the energization by and direction of behavior toward a positive stimulus. 'Avoidance motivation' is used to describe the energization by and direction of a behavior away from a negative stimulus (Elliot, 2006).

The definition of motivation includes two distinct parts: the 'energization' and 'direction' of behavior. Energization is used to describe the preliminary triggering of a response that instigates a behavior (Elliot, 1997). This is not meant to imply that an organism is in a resting state before the introduction of a stimulus; quite the opposite, there is a constant flow of orienting behaviors in response to ever-changing stimuli (Atkinson and Birch, 1970). 'Direction' refers to the way behavior is conducted in response to a stimulus and can be associated with the satisfaction of both biological and psychological needs (Elliot and Thrash, 2001).

The idea of movement is implicit in the definition of approach and avoidance motivation. Organisms move toward positively valenced stimuli and away from negatively valenced stimuli (Arnold, 1960; Corwin, 1921). However, it is important to note that an organism need not make a physical movement toward or away from the stimuli. Behavioral predispositions can also be considered approach and avoidance oriented, even though the overt behaviors may follow a different path according to the goals of the organism (Elliot and Church, 1997). In addition, it does not always have to be physical movement toward or away from a stimulus. For example, if an organism is already close to a positive stimulus, then staying near the stimulus can also be considered approach behavior. Similarly, if an organism is far from a negative stimulus, staying away can be considered avoidance behavior. Accordingly, moving toward or staying near a positive stimulus is conceptualized as approach behavior, while moving away from or staying away from a negative stimulus is conceptualized as avoidance behavior (Elliot, 2006).

The terms 'positive' and 'negative' are used to describe the evaluation of stimuli by an organism. Stimuli that are evaluated positively invoke approach behaviors in organisms, while stimuli that are evaluated negatively evoke avoidance behaviors in organisms. 'Positive' and 'negative' are comprehensive terms that are functionally equivalent to other dimensions such as pleasant/unpleasant and desirable/undesirable (Elliot, 2006).

The term 'stimuli' is used throughout this article to refer to any number of objects, opportunities, or events, whether observable in the physical world or internally generated by the organism (Elliot, 2006).

History

The approach–avoidance distinction has been utilized in a variety of different ways by scholars for over 2000 years, but its roots are in the field of philosophy. The Greek philosopher Democritus (460–370 BCE) proposed that human beings should follow 'ethical hedonism' and be guided by the pursuit of pleasure and the avoidance of pain (Elliot and Covington, 2001). Centuries later, Jeremy Bentham (1779/1879), a British philosopher, offered a similar 'psychological hedonism' in which humans actually are guided by the pursuit of pleasure and avoidance of pain. Although these concepts are similar, Bentham took the idea of ethical hedonism further by providing an explanation for behavior instead of a mere suggestion for how individuals should strive to behave.

Since the inception of the field of scientific psychology, the distinction between approach and avoidance motivation has

 http://dx.doi.org/10.1016/B978-0-08-097086-8.26071-6

been of great interest to researchers (see Elliot, 1999; Elliot and Covington, 2001). One of the founding figures of psychology, Wundt (1887) posited that pleasure and pain were psychological experiences brought into conscious awareness through the processes of cognition and sensation. James (1890) theorized that pain and pleasure were 'springs of action' that cause the energization of behavior and that pleasure served as reinforcement while pain served to inhibit actions. Freud (1915) suggested in his psychodynamic theory that organisms tend to seek pleasure and avoid pain. In addition, he described these tendencies as motivations that guide behavior and are regulated by the superego (Freud, 1923). These early theorists helped to move the focus from the distinction between pain and pleasure to the resultant approach and avoidance behaviors (Elliot, 2008).

These initial forays into the study of approach and avoidance motivation paved the way for other researchers to adapt this conceptualization for their own use. Thorndike (1911) proposed in his 'law of effect' that responses which resulted in 'satisfaction' were more likely to be repeated, while responses that resulted in 'discomfort' were less likely to be tried again. Jung (1921) suggested that extroverts were more likely to move toward social objects whereas introverts were more likely to move away from social objects. Pavlov (1927) distinguished between two distinct responses in his research on classical conditioning: an 'orienting' response (toward a stimulus) and a 'defensive' response (away from a stimulus). Lewin (1935) theorized that goal objects have positive or negative valences that attract or repulse organisms. Skinner (1938, 1953) differentiated between reinforcement, which led to strengthened responses, and punishment, which led to weakened responses.

Murray (1938) distinguished between 'adient,' positive needs which lead organisms toward objects, and 'abient,' negative needs which lead organisms away from objects. Hull (1943) described the approach–avoidance distinction as conditioned appetitive and aversive drives formed through positive and negative associations with stimuli, which lead organisms toward or away from stimuli. Miller (1944) theorized that conflicts result from incompatible valences and that organisms can be both drawn to and repulsed from the same goal object. Hebb (1949) suggested that differing levels of stimulation can result in different behavioral responses: stimulation below a certain level leads to approach behaviors, while stimulation above the level leads to avoidance behaviors. Rotter (1954) posited that individuals form expectancies from past experiences with rewards and punishments.

Maslow (1955) theorized that human beings have two basic sets of needs: growth needs that lead an individual to reach for more positive stimulation, and deficit needs that lead an individual to seek tension reduction in order to avoid negative stimulation. Cattell (1957) identified two innate motives: exploration (an appetitive motive) and escape to security (a nonappetitive motive). Heider (1958) conceptualized the difference between the words 'can' and 'may' in a similar way, claiming that 'can' implies that the person will succeed if they try, while 'may' implies that they will not be punished if they try. Rogers (1961) suggested that personal goals represent either a desire to move toward a positive stimulus or a desire to move away from a negative stimulus. Erikson (1963) differentiated between basic trust and mistrust in his Stages of Psychosocial Development. Eysenck (1967) theorized that introverts had high baseline levels of arousal and were therefore likely to be 'stimulus shy,' while extroverts had low baseline levels of arousal and were thus more likely to be 'stimulus hungry.' Bowlby (1969) differentiated between two types of attachment: secure attachment, which leads individuals to explore and seek challenges, and insecure attachment, which leads individuals to be cautious and concerned with safety.

This brief overview of psychological theorists is intended to establish the fact that the approach–avoidance distinction has been utilized throughout the history of psychology. In addition, this conceptualization has been present in every major theoretical orientation since the inception of psychology as a scientific field, from psychodynamic to behaviorism, humanistic, cognitive, biological, etc. (Elliot and Covington, 2001). It is also clear that there has been a historical lack of a widespread and useful conceptualization of the approach–avoidance distinction, which has led to a tremendous amount of variance in the way researchers describe the same concept. Researchers from different fields and backgrounds have applied the idea of a split between approach and avoidance motivation to their own theories in different ways, sometimes using different terminology, without explicitly defining the concept (Elliot, 2008). In addition, much historical work has focused on a variety of different specific concepts within the field of motivation. For example, research has centered on hedonism, drives, underlying motives of behavior, and valenced stimuli, but it is important to consider how the overarching approach and avoidance distinction can encompass all of these different types of research (Elliot, 2008).

Conceptualization of Approach and Avoidance Motivation

Approach and avoidance motivation have been observed across a tremendous variety of situations and in all different levels of species. Approach motivation has generally been linked to thriving, while avoidance motivation tends to facilitate survival. However, both are integral adaptive mechanisms that are necessary for the physical and psychological well-being of organisms (Elliot, 2006).

The approach–avoidance distinction can be seen in life forms ranging from the single celled to as complex as human beings. At the most basic end of the spectrum, the amoeba has exhibited approach and avoidance behaviors. For example, the introduction of a weak light stimulus results in a movement of protoplasm toward the light. In contrast, an intense light stimulus results in the opposite effect, a movement away from the light (Schneirla, 1959). These basic adaptive mechanisms are present at all evolutionary levels and serve to facilitate need satisfaction in organisms in everything from finding food and shelter to avoiding harm. Although the complexity of these behaviors varies substantially across different types of life forms, the underlying mechanisms of approach and avoidance motivation are present across species (Schneirla, 1959) and

have been documented in a number of different species (see Elliot and Covington, 2001). For example, Budaev (1997) implemented factor analysis to explore the patterns underlying behavior in guppies. Data showed that there were two distinct factors, approach and fear avoidance, and that they were stable over time. Further independent factor analyses conducted with different species have also supported the approach–avoidance distinction (Elliot and Covington, 2001). Research suggests that these approach and avoidance behaviors that lead organisms toward positive stimuli and away from negative stimuli have adaptive benefits (Schneirla, 1959).

Another argument for the approach–avoidance motivational distinction is the instantaneous nature of many approach and avoidance behavioral responses (Elliot and Covington, 2001). Even low-level organisms display immediate reflexive responses to stimuli. For example, the amoeba instantly displays the withdrawal response to bright light. It can be argued that the speed of the response, not just the ability to respond to stimuli, is part of the adaptive significance of such behavior (see Berntson et al., 1993; Orians and Heerwagen, 1992). Humans also experience a number of immediate approach and avoidance reflexive behaviors in response to external stimuli. Some of the most basic survival mechanisms can be categorized as either orienting (linked to approach) or defensive (linked to avoidance) (Dickinson and Dearing, 1979; Sokolov, 1963). For instance, the blink reflex is an automatic physiological response that occurs almost immediately after a startling stimulus such as a puff of air or bright light (Bradley and Vrana, 1993). This is an adaptive mechanism that can protect the eye from injury and prepare the body to cope with environmental threats (Lang, 1995; Öhman, 1997). The speed and strength of this response can vary in accordance with the motivational state of the individual; the reflex will occur more quickly and in greater strength when individuals are in a negative (avoidance) motivational state, in contrast with neutral and positive (approach) motivational states (Lang et al., 1990).

Humans tend to make positive or negative evaluative judgments of all stimuli they encounter (Osgood et al., 1957), both instantaneously and without conscious awareness (Bargh, 1997; Zajonc, 1998). Bargh et al. (1996) conducted a study on the 'automatic evaluation effect' where participants were subliminally primed positively or negatively with words and asked to pronounce other valenced words. The results showed that the subliminal priming of positively valenced words led to faster pronunciation of other positively valenced words. Researchers concluded that since participants were unaware of the primes, they had automatically processed the valence of the primed words despite the lack of instruction for them to do so. Although some researchers have suggested that these evaluations are a form of automatic cognitive processing (Fiske, 1982), others argue that they are an automatic reaction to stimuli, independent of cognitive processes (Kuhl, 1986; LeDoux, 1987; Zajonc, 1980). This automatic evaluation process is understood to immediately invoke approach and avoidance behavioral tendencies (Elliot and Covington, 2001). Researchers from a wide variety of fields (see Elliot and Covington, 2001) have explored the idea that these automatic evaluations can evoke instantaneous predispositions toward or away from stimuli. For example, Chen and Bargh (1999) asked participants to enact an approach behavior (pulling a lever toward themselves) or an avoidance behavior (pushing a lever away) when they saw a word. When the word valence matched the response valence (positive word for pulling the lever), participants reacted faster than when there was a discrepancy between the valence of the stimulus and the response, even when they were not asked to evaluate the words. Bargh and Chartrand (1999) posited that the automatic evaluation process leads to almost immediate approach and avoidance behavioral predispositions.

The behavioral predisposition created by automatic evaluation is not necessarily an explicit behavioral response (Elliot and Covington, 2001). Stimuli may produce a valenced automatic evaluation and preparedness for approach or avoidance behaviors (Arnold, 1960). However, the enacted behavior is not always linked with this evaluative response (Lang et al., 1997). In lower-level organisms, automatic evaluations may always result in predictable behavioral responses. On the other hand, humans may have goals that lead to behaviors not tied to the initial approach or avoidance response (Elliot and Covington, 2001). For example, if individuals walk by a coffee shop, they may experience an automatic approach reaction and take a step forward to enter. However, if they are trying to cut back on their caffeine intake, they may exhibit an overt avoidance behavioral response by turning around and walking away. As such, in order to predict the behavior of complex organisms such as humans, it is important to keep in mind that approach and avoidance motivation may be affected by differing goals on multiple levels (Cacioppo and Berntson, 1994), represented hierarchically (Elliot and Church, 1997) or on the same level (Miller, 1944).

A large portion of the research exploring the approach–avoidance distinction has focused on neuropsychological data. Davidson and colleagues (see Davidson, 1995) conducted a number of studies examining the localization of approach and avoidance motivation in the cerebral hemispheres. They found that greater resting activity in the left prefrontal lobe was associated with approach motivation and positive affect, while greater resting activity in the right prefrontal lobe was associated with avoidance motivation and negative affect. It should be noted that hemispheric activity was monitored using electroencephalograph (EEG) recordings and collapsed into a single scale of differences between the left and right hemispheres. This type of measurement is not ideal if we are to accept the independence of approach and avoidance as motivational constructs because it does not allow us to measure hemispheric activity when there are high levels of both approach and avoidance motivation (Ito and Cacioppo, 1999). However, further research has supported these findings by linking approach motivation with activation of the left hemisphere and avoidance motivation with activation of the right hemisphere using PET and fMRI studies (Murphy et al., 2003).

More recent studies have taken a different approach to studying approach and avoidance motivation at the neocortical level. Friedman and Forster (2005) used a behavioral measure to determine relative hemispheric activation after invoking

approach and avoidance anticipatory states by having participants complete an enacted behavior task. They found that anticipatory approach states led to greater right hemispheric activation (relative to left hemispheric activation), while anticipatory avoidance states led to greater left hemispheric activation (relative to right). However, when they examined approach- and avoidance-related arousal (rather than anticipation), the results were reversed. The results obtained when approach- and avoidance-related arousal was induced matched with earlier EEG studies on the localization of approach and avoidance motivation in different cerebral hemispheres. Continuing the behavioral measure research, Roskes et al. (2011) examined hemispheric activation by studying directional biases. After inducing approach motivational states, they found that participants displayed right-oriented behavioral biases, which implies left hemispheric activation. However, these results were only present when participants were under time constraints. More research is needed to elucidate the hemispheric activation differences associated with approach and avoidance motivation.

In addition to the aforementioned work on hemispheric differences in approach and avoidance motivation, research has also explored the idea that different areas of the brain may be associated with each construct. Historically, theorists have found that electrical stimulation of the brain can lead to the activation of 'pleasure centers' or feelings of pain (Delgado et al., 1954; Olds and Milner, 1954). These early data linked the septal area of the limbic system with pleasure, and the hypothalamic area of the limbic system with pain. More recent data have gone on to link the medial prefrontal cortex and nucleus accumbens to approach motivation and the amygdala and anterior cingulate cortex with avoidance motivation (Wager et al., 2003).

While both approach and avoidance motivation are integral mechanisms of our physical and psychological processing, they often have very different consequences. Approach motivation tends to enable thriving and frequently leads to positive outcomes (Elliot, 2006). Avoidance motivation, on the other hand, is linked to survival needs and a focus on negative stimuli, which can lead to stress and decrements in well-being (Elliot and Sheldon, 1997, 1998). In addition, while successful approach motivation can lead to positive outcomes, successful avoidance motivation can only lead to the absence of negative outcomes. Therefore, the presence of avoidance motivation can result in missed chances for positive growth and development (Elliot, 2006).

In sum, the conceptualization of approach and avoidance motivation is an integral part of research on explanation of behavior in all living organisms. It is an intuitive, instantaneous mechanism that is present in both reflexive and conscious behaviors and has proven biological underpinnings. For these reasons, this construct has been widely studied throughout history by scholars seeking to understand the causes of behavior.

Terminology

Throughout history, a variety of different terms have been used to describe the approach–avoidance distinction. Each deserves a brief overview of its unique conceptualization and usage (see Elliot, 2008; Elliot and Covington, 2001).

Early work in philosophy labeled the approach–avoidance distinction as 'hedonism,' distinguishing between two poles of pleasurable and painful experiences. This definition, utilized by the British Empiricists, has historically been quite narrow, only including physical sensations (Boring, 1950; Cofer and Appley, 1964); however, recently, in the field of psychology, 'hedonism' has been broadened to include other types of sensations, such as the experiences of accomplishment and failure, in addition to bodily feelings and affect (Kahneman et al., 1999; Rozin, 1999). The traditionally narrow definition of hedonism represents only a portion of the construct of approach and avoidance motivation, but the more recent expansion of the range of this definition is quite similar to the way approach and avoidance motivation is currently conceptualized (Elliot and Covington, 2001).

Some theorists have used the 'approach–withdrawal' distinction to examine visible behaviors in order to understand their motivational underpinnings. Schneirla (1959) argued for the use of observable behaviors as a tool for measuring motivation in order to achieve consistency when comparing lower-level and higher-level organisms. This conceptualization holds that organisms are acting on approach motivation when they move toward a stimulus and withdrawal motivation when they move away from a stimulus. More recently, Davidson and colleagues (Davidson, 1992; Sutton and Davidson, 1997; Tomarken et al., 1992) have broadened this definition to include behavioral predispositions as well as observable actions. For instance, an action tendency to approach a stimulus would be considered approach motivation even if there was no resulting movement toward the stimulus. These approach and withdrawal behavioral predispositions have been linked to activity in different hemispheres of the brain: approach tendencies are associated with activation of the left prefrontal cortex, while withdrawal tendencies are associated with activation of the right prefrontal cortex (Davidson, 1995; Roskes et al., 2011). The conceptualization of the approach–withdrawal distinction is similar to the approach–avoidance distinction. However, the approach–withdrawal construct focuses on the energization of behavior and only includes behavioral tendencies that are observable at a biological level. In contrast, the approach–avoidance distinction covers the energization and direction of action tendencies that are both psychologically and biologically based (Elliot, 2008).

Researchers in psychology have frequently used the terminology 'appetitive–aversive' when discussing a construct similar to the approach–avoidance distinction. Both of these conceptualizations focus on motivational valence: the underlying energization and direction of behavior toward positive stimuli and away from negative stimuli (Elliot and Covington, 2001). Craig (1918) suggested that appetites and aversions were experienced as internal states of readiness to approach a positive stimulus or to stay away from a negative stimulus. The use of the terms 'appetitive' and 'aversive' has been adopted by other theorists in the field of psychology (Tolman, 1932), and this operationalization has continued to be used in the areas of emotion and reflexive behaviors (Lang, 1995; Lang et al., 1997). Although the appetitive–aversive

distinction has gained prominence in certain areas of psychology, the conceptualization of approach and avoidance motivation is much more inclusive and can be used to examine a wider range of phenomena (Elliot, 2008).

The terminology 'approach–avoidance' was first used by Lewin (1935) in his work on Field Theory. He suggested that all stimuli have attractive or repulsive properties, which lead organisms to approach or avoid them. These approach and avoidance responses stem from the internal states of the organism and are often associated with the satisfaction of survival needs. Miller (1944) also adopted this conceptualization, although his research focused on the physical movement toward or away from objects. McClelland and colleagues (McClelland, 1951; McClelland et al., 1953) continued using this operationalization of the approach–avoidance distinction but focused on the dispositional preferences of the organism for states or experiences, such as the need for achievement. These theorists all considered the approach–avoidance distinction applicable to the underlying mechanisms of behavior and cognitive processes (Elliot and Covington, 2001).

Although each terminologically distinct conceptualization has its own explanatory strengths, it is best to adopt the most comprehensive definition for the approach–avoidance distinction. Historical work on 'hedonism' has focused too narrowly on only sensory and affective phenomena, while 'approach-withdrawal' has overemphasized observable processes and physical movement. The 'appetitive–avoidance' distinction is similar to 'approach–avoidance,' but the latter has been used more widely in the literature and is easier to understand for those unfamiliar with the field. In addition, the current usage of the 'approach–avoidance' distinction has evolved to become a broad explanatory tool for different types of phenomena ranging from reflexes to motivational states, which makes it the most comprehensive terminological conceptualization (Elliot, 2008).

Concluding Statement

As illustrated, the approach–avoidance distinction provides a conceptual foundation for the scientific study of motivation. Approach and avoidance motivation are fundamental to the study of behavior in humans and lower organisms and have been a topic of much discussion for over 2000 years in a variety of different fields. In order to fully understand the determinants of behavior, it is important to have a widely used conceptualization of approach and avoidance motivation.

Awards, Public Recognition, and Evaluation

Abstract

Scientific authority or the power and legitimation to contribute in scientific debates is granted by the recognition of peers and the public. To be granted recognition and esteemed by colleagues the visibility of discoveries, arguments, or theories are a prerequisite. One form of distinction manifests by being read, cited, or referred to in speeches, i.e., being part of the academic discourse. Public evaluation and distinction manifests in practices of issuing awards, grants, or prizes to researchers and their institutions; issuing honorary degrees to academics and other public figures, but also by evaluating and ranking research, researchers, and their institutions.

Introduction

Scientific authority or the power and legitimation to contribute in scientific debates is granted by the recognition of peers and the public. To be granted recognition and esteemed by colleagues the visibility of discoveries, arguments, or theories are a prerequisite. In this article, the most visible element of such recognition – the awarding of prizes – will be discussed. Public distinctions such as awards, honorary degrees, and other public appraisals help to establish academic recognition and at the same time organize the academic field. Awards make peer recognition, hierarchies, and hegemonic scientific discourses visible. Systematic studies dealing with the contemporary or historical role of awards in the social and behavioral sciences are rare. Rather, existing literature either deals with histories of single prizes, or more broadly with the phenomenon of reputation and recognition (H.S. Becker, P. Bourdieu, R. K. Merton). Taking this lack of empirical examination into account the following lines will shortly elaborate on functions of recognition and public distinction in the academic field before providing some historical background to the awarding of prizes and offering a tentative typology of awards in the academic field. A selection of international prizes will be depicted before focusing on atypical exponents such as honorary degrees and forms of collective distinction such as higher-education rankings.

Recognition and Reputation

Scientific authority or the power and legitimation to contribute in scientific debates is granted by the recognition of peers and the public (Bourdieu, 1976). Prizes, awards, and other forms of public distinction are compelling signs of public and peer recognition. Not only are these an institutionalized sign for the acceptance of the work of a researcher, but they also contribute to making research and researchers visible in the public sphere. To be granted recognition and esteemed by colleagues the visibility of discoveries, arguments, or theories are a prerequisite. In Howard S. Becker's (1982) description of the art world the acceptance of an oeuvre depends on whether one is working in an accepted style or not. Similarly, the use of specific methods, theoretical standpoints, and arguments in the social and behavioral sciences tend to influence the recognition bestowed upon a colleague inside a narrow scientific community. The desire for recognition – manifested by being read and cited – is a main motivation for academics (Hull, 1988).

A latent but nonetheless powerful form of distinction consists of a researcher being read, quoted in print, or referred to in oral communication, i.e., being part of the academic discourse. Histories of disciplines inevitably know something such as classics or key figures that have obtained 'reputational immortality.' This status becomes manifest through legacy-forming mechanisms such as naming an award, foundation, building, or lecture hall, but also a theory, school of thought, or controversy by the name of a researcher. This kind of scientific reputation is also shown by including researchers in textbooks, specialized encyclopedias, or histories of a discipline. On a less prominent level there is the 'Festschrift' and obituaries honoring the work of an academic. Of similar nature are commemorative events taking place in the memory of a particular person. Like in the field of arts (Lang and Lang, 1988) postmortem reputation is only established if the deceased reached a critical mass of publications that was conserved and distributed. Also, the study of 'classics' and other dead scholars could make use of records such as mail correspondence with prominent colleagues, notes, or unfinished manuscripts bequeathed upon death that can contribute to the memory of a particular person.

Patterns influencing the reward system in science deviating from meritocratic ideals show that public recognition of science does not only reward talent, productivity, or the contribution to the advancement of a scientific field but that institutionalized cultural capital plays a major role in the allocation of awards. Merton (1968) described one of these systematic deviations based on Harriet Zuckerman's work on Nobel laureates, which showed that in science "eminent scientists get disproportionately great credit for their contributions to science while relatively unknown scientists tend to get disproportionately little credit for comparable contributions" (Merton, 1968: 2). The first part – the overevaluation of recognized researchers – has been remembered as the Matthew effect. Rossiter (1993) described the (female) equivalent as the Matilda effect, where she specifically highlighted the systematic underappreciation of the work of women in scholarship.

These systematic unbalances in recognizing the work of scholars that ought to be meritocratic have resulted in the practice of creating prizes for those who have not received the

recognition they were supposed to get, as an illustration one could mention the so-called alternative Nobel Prize distinguishing improbable research (IGNobel, 2014).

Awards, Medals, and Prizes

What Bourdieu calls objectified symbolic capital are mechanisms of public evaluation and distinction that fulfill the role of distinguishing an individual or a piece of research from others explicitly. The awarding of such a distinction is enacted in a public ritual and, in the social and behavioral sciences, it manifests in practices of issuing awards, grants, or prizes to researchers and their institutions; issuing honorary degrees to academics and other public figures; but also – more recently – by evaluating and ranking research, researchers, and their institutions. Awards and prizes can relate to past research, teaching, or an entire oeuvre. Prizes can, however, also be awarded for prospective or ongoing research taking the form of research grants or (prestigious) scholarships. A prominent example for the latter are research grants issued by the European Research Council, established in 2007, which awards resources of up to € 2.5 million and is often referred to as an award. Honorary degrees have the function to honor at the same time the recipient of the honorary degree and the institution granting the honors by claiming a relationship between the institution and the person having received the degree.

In the arts and humanities, the practice of awarding prizes, medals, and other forms of distinction goes back at least to "Greek drama and arts competitions in the sixth century B.C." (English, 2002: 1–2). A broader array of prizes was established in the early Renaissance (English, 2002: 2) and in the eighteenth century another impetus came from royal and national academies, professional associations as well as learned societies (English, 2002: 2). In the eighteenth century, a series of contests awarding solutions to societal/scientific questions were advertised. These were organized to promote research in certain fields, a practice which has been taken up again recently by, for example, the Longitude Prize (Nesta, 2014). This latter prize takes reference to the historical Longitude Act of 1714 that offered a prize for a solution of the problem of longitude.

In contrast to that the distinctions offered by academies of science, which were established since the beginning of the seventeenth century, is mainly of symbolic nature and manifests in granting seats in the academies. Usually, ordinary members of these institutions vote to select a new member. The number of seats in academies of science being restricted, only a fixed number of individuals can hold a seat at the same time. This leads to the so-called phenomenon of the 41st chair (Merton, 1968). The 41st chair refers to the limitation of 40 seats in the Académie française and the resulting situation that a great number of distinguished personalities were not admitted into the Académie, such as Descartes, Flaubert, Molière, Pascal, Proust, Rousseau, Stendhal, or Zola. "In all [academies] there are occupants of the 41st chair, men outside the Academy having at least the same order of talent as those inside it" (Merton, 1968: 1).

With the establishment of the Nobel Prize in the early twentieth century, academic distinctions received an international dimension. The internationalization of scientific prizes in the late nineteenth century coincided with the internationalization of academia and the creation of international scientific associations. Ever since, the number of distinctions, awarded by an increasingly large variety of funders, grows continually from one year to the next.

A Typology of Awards

Although one could try to differentiate prizes from awards, for example, along the lines of whether a researcher needs to enter a competition to win, or whether the selection undergoes a nomination process and whether a monetary reward is included or not, empirical evidence suggests that there is no clear differentiation between these terms. However, a typology of awards, medals, and prizes can be suggested that also helps to differentiate between varying functions of these distinctions for the recognition of researchers, science, and associated institutions. Prizes and awards can thus be distinguished by funder; award category; disciplinary, geographical, and institutional scope; or selection procedure. These dimensions cannot be perceived as comprehensive as they overlap and, in many instances, complement each other.

Funder	*Award category*	*Boundaries of eligibility*	*Selection procedure*
Academies of science	Life work	Locality (national–international)	Peers
Foundations	Past research	Membership	Nonresearchers
Associations	Ongoing research	Disciplinary boundary	Competition
Companies	Future research	Nonacademic	Nomination
	Output	Academic	Transparency

Funders can broadly be differentiated between academic and nonacademic institutions, or on a slightly different level, whether a prize is given by members of the scientific community to honor a member thereof, or whether it is an external organization issuing an award to scholars (and other persons). Whereas prizes by sections of academic associations, learned societies, and the like are often quite insignificant in their monetary value their reputational value within a specific scientific community might be high. Thus the main function of these prizes are to honor the recipient of the award and bestow him/her with scientific capital and the (peer) legitimation to take a leading role in ongoing debates of the awarding epistemic community. Other relevant academic funders are international scientific associations, universities, and scientific journals. In contrast to that, there are a number of nonacademic institutions such as cities, regions, or ministries as public bodies on the one hand, and, on the other, private institutions like foundations, NGOs, or corporations that award prizes to scholars. Private institutions might carry out research and/or fund research, however, they are usually only operating on the boundaries of the academic field. The awards given by private funders often reflect aims of these organizations or, in some cases, have the function to influence the public perception of a company.

Prizes can be awarded in a multitude of categories. One (functional) distinction is between past (reaching from single studies to life work), ongoing, or future research. This distinction can be applied to prizes for young scholars, for lifework, or research grants for promising future research. Another category for awards – which in some cases might overlap with the previous differentiation – is along the lines of different types of outputs. The differentiation there can run along the lines of, for example, best book or best paper award, prizes for innovative teaching but also distinctions for museum installations would form such a category.

The 'boundaries of eligibility' describe the phenomenon that only members of certain groups are eligible to receive a certain award thus restricting competition. The geographical scope of an award is characterized by the dichotomy between locality and internationality. Local prizes restrict participation or nomination for example, to members of a university or researchers of a region, city, etc. and often serve to promote and fund local research. By defining thematic priorities, such local prizes can help to establish a research profile for a region, university, etc. Eligibility can also be restricted by requiring membership to specific organizations, associations, etc. In contrast to that are prizes that allow for any person to be eligible for nomination. In this latter category the number of potential nominees is, however, restricted by traditions connected to prizes, dominant ideas concerning the kind of research, and researcher to be distinguished and, the restricted scope of potential nominees known to those involved in the selection procedure. Third, disciplinary or thematic boundaries are defined in call texts, the general aims of an institution, or distinction, e.g., a prize can be designed for cognitive psychology, or open to all disciplines. Especially for international distinctions the boundaries of a prize are even broader, as some awards are of more general nature aiming at distinguishing personalities for their contribution to the 'advancement of humanity' at large. Fur these types of awards members of other social groups than scholars – such as political activists, journalists, writers, and public intellectuals at large – are equally eligible.

Two dimensions concerning the selection of award winners shall be discussed: First, the technical procedures and second, patterns influencing the reward system in science. Broadly speaking two technical procedures exist; the selection through application and the selection through nomination. In both scenarios a more or less complex set of actors, boards, referees from within the academic field or not, but also regulations and traditions associated to the prize need to be taken into account. The social procedure leading to the selection can, for many prizes and awards, be compared to that of peer review procedures leading to fellowships as studied for example by Lamont (2009). The nomination and selection by a board consisting of scholars and nonscholars is a pattern found prototypically for the selection of awardees of international distinctions. The combination of competition and peer review, in contrast, is characteristic for research grants and young researchers' awards. Another promising distinction for the study of awards is the degree of transparency chosen in the selection procedure. Transparency concerning the selection of a winner is not a necessary prerequisite for a prize to be esteemed of high quality. Some institutions try to legitimize their awards by offering explicitly transparent procedures.

International Prizes and Awards

In the social and behavioral sciences, a series of international prizes were established since the end of World War II. To become an asset to a scholar being distinguished with an award it needs continuous funding, visibility inside the relevant peer-group, and a recognition of its own.

International scope and the public recognition of a prize are not only serving the renown of researchers, but are also a resource for local prestige. It is well known, for example, that the Nobel Prize is Swedish. To serve the renown of the awarding institution – and the researcher – awards need to establish a reputation of their own. Awards obtain their reputation through input- and output-legitimizing procedures. High monetary endowment is an element that can help to obtain reputation, as it may increase the public visibility of a prize. However, the correlation between the monetary value and (public) recognition of a prize is not positive. Prizes with low endowment can become more reputable than awards offering a more significant reward, e.g., the Fields Medal in mathematics has a comparably low monetary endowment, is, however, regularly referred to as the Nobel for mathematics.

Transparent procedures leading to a distinction are another criterion, which may increase input legitimacy of a prize. This may include making nominations public and offering insight to the process leading to the selection of an awardee. However, there are examples where transparency is not given and the reputation of a prize mainly depends on the successful output – i.e., the continuous selection of broadly accepted awardees. Most prominent is the Nobel Prize, where "nominations, evaluations, deliberations, and final decisions concerning the prizes were to be kept secret" (Crawford, 2002: 3). Further, at the time of nomination it is unclear who was invited to propose nominations besides those with a permanent entitlement to nominate. In the case of the Nobels, only historical cases older than 50 years can be accessed and scrutinized. Ultimately, it is the output – i.e., selection of individuals and institutions that stand the moral, professional, and public scrutiny that will have the strongest influence on the reputation of the award and award-giving institution. Institutions awarding prizes thus have a high interest in selecting laureates that already have a certain reputation and will not deceive the expectations of the award givers. In the case of the Nobels, this may explain the increasing average age of awardees over time. Although the Nobels are awarded for the best research in a year, by choosing individuals that have already accomplished a great amount of their lifework the probability of unexpected future turns – that might then be associated with the Nobels – are low. In contrast to offering a high monetary endowment to increase public visibility, building a reputation of an award based on the achievements, and recognition of the researchers selected takes time. The character of a prize can also be established through other forms of public distinction: for example, in literature the Booker prize gained its reputation by "delivering annual scandals" (English, 2002: 114).

The Nobel Prize, one of the first international awards, managed to gain reputation in a short period of time. In the

social and behavioral sciences the 'Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel' was only introduced in 1969. Since, 74 laureates, thereof one woman, were distinguished with this prize. Although the endowment of $ 1.2 million in 2013 is higher than most other research prizes the awardees often only receive parts thereof as the prize can be divided among three scholars. The high reputation and public awareness for the Nobel Prize has transformed it into a reference for other prizes especially in domains where no Nobel is given. In mathematics, as mentioned, the Canadian Fields Medals compete with the – much higher endowed – Norwegian Abel prize for status of Nobel Prize in mathematics. A prize deliberately aiming at rewarding fields that are not covered by the Nobel Prizes is the John W. Kluge Prize hosted by the Kluge Center in the Library of Congress and first awarded in 2003 to Leszek Kolakowski. It is endowed with $ 1 million and covers disciplines such as history, philosophy, politics, anthropology, sociology, religion, criticism in the arts and humanities, and linguistics. Next to these Nobel substitutes there are also Nobel Prizes in categories, such as literature and the peace prize that were awarded to individuals related to the social sciences. Among others, the latter was awarded to three women with a more or less close relationship to social sciences: Jane Addams (1931), Emily Greene Balch (1946), and Alva Myrdal (1982) (for details on these three see Misztal, 2009). Also, Theodore Mommsen (1902) and Bertrand Russell (1950), a historian and a philosopher, received the Nobel Prize in literature.

In the natural sciences these international prizes awarded by academies and foundations have most recently been complemented by a series of highly endowed awards funded mainly by US-American, Russian, and Asian Internet entrepreneurs. These latter prizes define as their goal to make the sciences more visible and to raise the awareness of excellent science in certain fields. Among these prizes we find the 'Breakthrough Prize in Life Sciences' (2013) and the 'Fundamental Physics Prize' (2012) both endowed with $ 3 million or the 'Tang Prize' (2013) endowed with over $ 1.5 million (Merali, 2013). The exceptionally high monetary value of these prizes is complemented by a presentation of the laureates reminding events staged for performing arts. The individuals or institutions are put into the center of attention with great media impact. Such presentations provide the opportunity to present the prizewinner as well as the company/brand/institution hosting the prize.

The functions of awarding prizes are thus at least threefold: honoring the recipient, promoting the awarding organization and improving its public profile, and informing a larger public on scientific issues or the aims of an organization.

International Social Science and Humanities Prizes

Historically the first renowned international disciplinary prize was the already mentioned Nobel Prize in economics established on an annual basis in 1969 and first awarded to Ragnar Frisch and Jan Tinbergen for applied dynamic models for the analysis of economic processes (see Nobel Media, 2014). A prize with an even longer tradition is the Italian Antonio Feltrinelli Prize given by the Accademia Nazionale dei Lincei, which names itself the oldest academy founded in 1603. The Feltrinelli Prize is split in distinctions limited to Italian citizens and an international prize. In contrast to the Nobel Prize, the disciplines covered rotate since 1950 on a yearly basis and include the arts, music, literature, history, philosophy, medicine, and physical and mathematical sciences.

Other examples for awards of multidisciplinary nature that remain restricted to the social sciences and humanities, are for example, the European Amalfi Prize for sociology and social sciences (Premio Europeo Amalfi per la Sociologia e le Scienze Sociali) established by the Italian Association of Sociology and first awarded in 1987 to Norbert Elias. The selection was made by a jury that included distinguished social scientists. Another highly renowned prize is the Prince of Asturia Prize that is among others awarded in the categories of social sciences as well as communication and humanities. In the social sciences, it was first awarded in 1981 to Román Perpiñá. More recently we saw the creation of the Holberg Prize by the Norwegian government to distinguish research in the arts and humanities, social science, law, or theology, which is awarded 4.5 million Norwegian Krone. The first awardee in 2004 was Julia Kristeva.

Prizes of even broader scope that are among others relevant for social and behavioral sciences are those that commemorate humanistic goals. These prizes usually do not have disciplinary boundaries and are also awarded to personalities coming from nonacademic fields. Examples for early prizes of this category would be the Heine Prize, which is a biannual prize established by the city of Düsseldorf to commemorate the 175th birthday of Heinrich Heine and currently endowed with € 50 000 or the Peace Prize of the German Book Trade first awarded in 1950 with the aim to "reintroduce humanist thought into society" (Book Prize, 2014) in Germany. In 1958, the Erasmus Prize was installed "for a person who has made an exceptional contribution to culture, of scholarship, in Europe and beyond" (Erasmus Prize, 2014). It was first awarded to the people of Austria and was later awarded to distinguished scholars such as Claude Lévi-Strauss or Jürgen Habermas.

Honorary Degrees – Honoris Causa

Honoris causa or degrees awarded 'for the sake of honor' are distinctions honoring public figures for general societal achievements, support for academia, and/or for academic merits. Inside the scientific community, the practice of awarding honorary degrees is controversial. By borrowing names of academic merits (Bachelor, Masters, Doctor) honorary degrees suggest a honorification of academic work. The practice of awarding such degrees to individuals that have not gathered merits in academia, however, is inconsistent with idealized conceptions of science. By granting such degrees to (potential) donors, politicians, and other public figures to gain their (monetary) support, it is argued that the ideals of free and uninterested research are broken.

The tradition of granting honorary degrees is traced back to fifteenth century England, where academic degrees were a form of currency for being granted recognition by the Church and the State (Buxton and Gibson, 1935: 84). The earliest traces of an honorary degree lead to Lionel Woodville, Dean of Exeter, the brother-in-law of Edward IV and a future bishop who was awarded the first honorific degree in Oxford in 1478 or 1479.

These early honorary degrees furthermore granted considerable privileges in the university (Buxton and Gibson, 1935) whereas in modern times privileges are more restricted and are comparable to those granted to alumni (e.g., donating into alumni funds, using certain sporting facilities, faculty clubs, etc.).

The USA has a strong tradition of granting honorary degrees. Next to demonstrating proximity between leading public figures and academia, such honors also had the function to reward wider societal engagements. The first honorary doctorate is traced back to the sixth president of Harvard College in 1692, Increase Mather (Lady, 1967: 198). The title allowed Harvard College to become a University and grant doctoral degrees of its own. After independence in the late eighteenth century colleges conferred degrees to many military and political leaders. George Washington for example, received five awards (Lady, 1967: 199). In the 1870s, more honorary than earned PhDs were awarded in the USA (see Lady, 1967: 200), which even led to universities adopting regulations limiting the awarding of such degrees at the end of the century. Other institutions like the Massachusetts Institute of Technology, Rice, Cornell, Stanford and military academies have never or only in very rare circumstances awarded honorary degrees (see MIT News, 2001; Freiherr, 1979: 23).

Ranking Research

Public distinctions on the individual level come in the form of awards, prizes, medals, and the like. On the collective level public evaluation of research comes in the form of rankings of institutions of higher education, academic journals, etc. It is a phenomenon of the twentieth and twenty-first century. The rankings contribute in establishing a (seemingly) rationalization of the hierarchy inside and between institutions, researchers, and disciplines. The evaluation and, henceforth, ranking of research based on a limited number of indicators is often attributed to broader developments in the organization of knowledge-systems that took place since the end of World War II. The introduction of the so-called entrepreneurial university, public management, and a more general lack of legitimacy to spend public funds contributed to establishing a comprehensive system of public evaluation of research. Also, the massive expansion of the tertiary educational sector and the consequential growth of the academic field since the 1950s brought an unprecedented increase in competition among educational and research institutions on a global scale.

In the last decade, the Times Higher Education World University Rankings, the Academic Ranking of World Universities, also known as the Shanghai Ranking, and the QS World University Rankings are among the most influential rankings of universities on a global scale (for a comparison see StatSilk, 2014). The rankings use different sets of indicators to compare institutions and combine these with peer review procedures and surveys among researchers and students. On the European scale the Centre for Higher Education Development, founded by the German Rector's Conference and the Bertelsmann Foundation, evaluates German Universities since 1998 and selected universities on a European scale since 2010. In contrast to these global rankings, national mechanisms of collective evaluation that compare the performance (or what is understood as being an academic performance) are used by policy-makers to take decisions concerning the distribution of funds, the establishment of programs of excellence or the penalization of underperforming institutions.

Public evaluation of research does not only take place on the organizational level but is also practiced on the individual level. The evaluation of performance based on predefined indicators, e.g., the publishing of a certain amount of journal articles in a specified timeframe, is used to rationalize personnel decisions such as awarding tenure. A more open approach to evaluation is taken by social media platforms where – similarly to the rating of holiday destinations – regional, national, and international Internet-based services have developed portals for the evaluation of courses, lecturers, and professors.

Axiomatic Theories

Abstract

After considering the historical background of axiomatic methods since the beginning in ancient Greece, this article covers the main ingredients of methods for axiomatizing theories in mathematics or an empirical science within a standard set-theoretical framework. This approach has a natural division into the following steps. First, identify the primitive concepts of the theory being axiomatized; second, state explicitly the prior mathematical basis assumed; third, state the axioms; fourth, characterize models of the theory and give a definition of isomorphism of two such models. Examples and applications are given for various social–science theories, with an emphasis on measurement problems for such concepts as preference, subjective probability, utility, and stimulus intensity. Formal game-theory models for economics and quantum models for finance and decision making are briefly discussed.

After considering the historical background of axiomatic methods since the beginning in ancient Greece, this article covers the main ingredients of methods for axiomatizing theories in mathematics or an empirical science within a standard set-theoretical framework. This approach has a natural division into the following steps. First, identify the primitive concepts of the theory being axiomatized; second, state explicitly the prior mathematical basis assumed; third, state the axioms; fourth, characterize models of the theory and give a definition of isomorphism of two such models. Examples and applications are given for various social–science theories, with an emphasis on measurement problems for such concepts as preference, subjective probability, utility, and stimulus intensity.

Axiomatic development of theories is common practice in pure mathematics and is also now widely used in many sciences. The main ingredients of the methods for axiomatizing theories are the following: statement of the primitive concepts of the theory, statement of the prior mathematics basis assumed, statement of the axioms, characterization of models of the theory, and a definition of two such models having the same structure. Theories formulated in this way can easily satisfy the standard set-theoretical approach to axiomatization. The further step of formalizing the language of the theory, especially in the case of elementary theories, can lead to specific positive and negative results about the axiomatizability of theories in restricted languages.

Historical Background

Of all the remarkable intellectual achievements of ancient Greek civilization, none has had greater subsequent impact than the development of the axiomatic method of analysis. No serious traces are to be found in the earlier civilizations of Babylon, China, Egypt, or India. The exact history of the beginnings is not known, but elements that can now be identified emerged in the fifth century BC. A good reference is Knorr (1975). What can be said, and is important for the subsequent discussion here, is that, already in the next century, the fourth century BC, the detailed and elaborate theory of proportion of Eudoxus emerged in quite a clear and definite axiomatic form, most of which is preserved in Book V of Euclid's *Elements* (Euclid, 1925). What is important about Eudoxus's work, and even the commentaries of the work of this time, for example, by Aristotle, in the *Posterior Analytics* (1994 74a–17), is that the theorems were proved, not for single geometric objects, but for magnitudes in general, when applicable. The recognition of the correct abstraction in the general concept of magnitude, its technical and thorough implementation by Eudoxus and the philosophical commentary by Aristotle, represent a genuinely new intellectual development. The language of Eudoxus's famous Definition V in Book V of Euclid's *Elements* matches in its abstractness and difficulty the standards of modern axiomatic theories in mathematics and the sciences.

Definition 5 *Magnitudes are said to be in the same ratio, the first to the second and the third to the fourth, when, if any equimultiples whatever be taken of the first and third, and any equimultiples whatever of the second and fourth, the former equimultiples alike exceed, are alike equal to, or alike fall short of, the latter equimultiples respectively taken in corresponding order*.

The codification of the Greek axiomatic approach in Euclid's *Elements* was a great success and remained almost unchallenged until difficulties in the details were found in the eighteenth and nineteenth centuries, as discussed later.

Various scientific examples of axiomatic theories existed already in ancient Greek times and, of course, from the Greek standpoint, they were regarded as essentially homogeneous with the axiomatic theory of geometry, no sharp distinction being made between geometry and mechanics, for instance. A good example is Archimedes' set of partial qualitative axioms for measuring weights on balances. This is undoubtedly the first partial qualitative axiomatization of conjoint measurement, a form of measurement that has received much axiomatic attention and manifold applications in modern theories of measurement in the social sciences. (For detailed treatment of conjoint measurement, see Krantz et al., 1971. *See* Measurement Theory: Conjoint.)

Other early examples of axiomatic theories aimed at empirical matters can be found in the large medieval literature on qualitative axioms for the measurement of weight (Moody

and Clagett, 1952). Even more impressive examples are to be found in the medieval literature on physics. Some of the most subtle and interesting work is that of Nicole Oresme (1968) in the fourteenth century. (See especially his treatise, Tractatus de Configurationibus Qualitatum et Motuum.) What is surprising is Oresme's unexpectedly subtle approach in a geometrical framework to the phenomena of intensive qualities and motions. An example for Oresme would be that of a surface being more or less white.

Finally, in the geometric axiomatic tradition of analyzing phenomena in natural science, the two great late examples of deeply original work were the seventeenth century treatises of Huygens' *The Pendulum Clock* (Huygens, 1673/1986) and, of course, as the second example, Newton's *Principia* (Newton, 1687/1946). Both Huygens and Newton formulated their axioms in the qualitative geometric style of Euclid and other Greek geometers 2000 years earlier.

Here is the English translation from the Latin of Newton's purely verbal formulation, in the language of proportion, of his first three justly famous axioms or laws of motion:

> LAW I
> Every body continues in its state of rest, or of uniform motion in a right line, unless it is compelled to change that state by forces impressed upon it.

> LAW II
> The change of motion is proportional to the motive force impressed; and is made in the direction of the right line in which that force is impressed.

> LAW III
> To every action there is always opposed an equal reaction: or, the mutual actions of two bodies upon each other are always equal, and directed to contrary parts. Newton (1687/1964), p. 13

Axiomatic Geometry in the Nineteenth Century

Without question, development in axiomatic methods in the nineteenth century was the perfection and formalization of the informal Greek methods that had dominated for so many centuries. The initial driving force behind this effort was certainly the discovery and development of non-Euclidean geometries at the beginning of the century by Bolyai, Lobachevski, and Gauss. An important development later in the century was the discovery of Pasch's (1882) axiom as a necessary addition to the Euclidean formulation. Pasch found a gap in Euclid's work, which required a new axiom, namely, the assertion that if a line intersects one side of a triangle, it must also intersect a second side. This was just the beginning for Pasch. He created the modern conception of formal axiomatic methods, which has been the central aspect of the model for axiomatic workup until present times. The axiomatic example in geometry that had the most widespread influence was Hilbert's *Grundlagen der Geometrie*, first published in 1897 and still being circulated in later editions (Hilbert, 1956).

Ingredients of Standard Axiomatic Practice

Building, especially, on the work in the later part of the nineteenth century in axiomatizing geometry, early in the twentieth century there was widespread axiomatization in mathematics and, to a lesser extent, in the empirical sciences. The main ingredients of the methods for axiomatizing theories were the following: statement of the primitive concepts of the theory, statement of the prior mathematics basis assumed, statement of the axioms, characterization of models of the theory and a definition for isomorphism of two such models, proof of a representation theorem when possible, and, finally, some analysis of invariance of the models of the theory.

Before turning to an explicit discussion of these ingredients, it is worth noting that the emphasis should really be on models of the theory, which is what axiomatizing a theory makes clear. It is the models of the theory, i.e., structures, that satisfy the theory, as explained in the section Independence of Axioms, and that exhibit the nature of the theory, whether it be in geometry, economics, psychology, or some other science. (For an elementary, but detailed, account of the concepts discussed in this section, see (Suppes 1957/1999, Chapters 8 and 12).)

Primitive Concepts of a Theory

The first point to recognize in axiomatizing a theory is that some concepts are assumed as primitive. Their properties are to be stated in the axioms, and, therefore, it is important to know how many such concepts there are and what their general formal character is, such as relations, functions, etc. In Hilbert's axioms for elementary plane geometry, the five primitive concepts are those of point, line, plane, betweenness, and congruence. In contrast, in psychological theories of measurement, an ordering of the stimuli or other phenomena is almost always assumed – in this case, a weak ordering, that is, a binary relation that is transitive and connected, rather than the geometric ordering of betweenness.

In addition to a primitive concept of ordering, there are other relations, for example, a primitive concept of the comparison of stimulus differences or an operation of combination for extensive measurement, as in the case of subjective probability. These measurement examples also apply to a large literature on utility and subjective probability in economics. In psychological theories of learning, even of the simplest nature, one would need such concepts as that of stimulus, response, and a conditioning relation between stimulus and response. Theories without much more elaboration would require the important concept of similarity or resemblance, in order to develop a theory of the fundamental psychological phenomena of generalization, discrimination, and transfer.

There are also important theories that use much simpler primitive concepts. A good example would be the theory of zero-sum, two-person games in normal form. The primitive concepts are just that of two nonempty sets X and Y that are arbitrary spaces of strategies for the two persons and a numerical function M, defined on the product space $X \times Y$. The intuitive interpretation of M is that it is the payoff or the utility function for the player whose space is X. The negative of that is the payoff for the player whose space is Y. Later, a representation theorem is given for finite games of this sort.

Axioms as Defining Theories

As is widely recognized, axioms are what intuitively characterize a theory, whether it be of geometry, game theory, or a psychological theory of measurement. From a formal standpoint, something more can be said. The essence of the matter is that, to axiomatize a theory is to define a certain set-theoretical predicate. This is just as valid in the empirical sciences as in pure mathematics. The axioms, of course, are the most important part of such a definition.

Because the theory of weak orderings is used widely in both economics and psychology, as part of the theory of choice, it will be useful to give a formal definition and, therefore, the axioms for a weak ordering.

Definition 1 *Let A be a nonempty set and R a binary relation on A, i.e., let R be a subset of the product space* $A \times A$. *A structure (A, R) is a weak ordering if and only if the following two axioms are satisfied, for every a, b and c in A:*

Axiom 1 *R is transitive on A, i.e., if aRb and bRc then aRc.*

Axiom 2 *R is connected on A, i.e., aRb or bRa.*

There are various general methodological and folklore recommendations about the way in which axioms should be written – clarity, lack of ambiguity, and simplicity are familiar. More substantive results about the form of axioms are discussed in the section Theories with Standard Formalization or first-order formalization. There are many definite mathematical results about the form of axioms, some of which are also discussed later.

Independence of Axioms

An early and important substantive recommendation is that the axioms be independent, i.e., none can be derived from the others. The question then arises from a methodological standpoint: how is independence to be established? The answer is in terms of models of the axioms. To make the matter still more explicit, consider possible realizations of the theory. These are set-theoretical structures that have the right form. For example, in the case of weak orders, a possible realization is an ordered pair consisting of a nonempty set and a binary relation on that set. Such an arbitrary pair is called a possible realization because as a possible realization it is not a model of the theory unless the axioms of the theory are also satisfied. An obvious example of a model of the theory of weak ordering is the pair consisting of the set of positive integers and the relation of weak inequality $\geq$.

The independence of a given axiom of a theory is established by finding a possible realization of the theory in which all the axioms, except the particular one in question, are satisfied. The deductive argument to show that this yields a proof of independence is intuitively obvious and will not be made in a more formal manner here. However, the essence is that if the concept were not independent, but definable, then it would necessarily hold in the model, just like the remaining axioms, and so a contradiction of its both holding and not holding in the given model would be obtained. Therefore, by reductio ad absurdum it must be independent. It will be useful to consider an example or two.

To show that the axiom of connectedness for weak orders is independent of the axiom of transitivity, it is necessary to take a possible realization that is also a transitive relation. Let $A = \{1, 2, 3\}$ and $R = \{1, 2\}$. In other words, R is just the strict numerical $<$ relation on the subset $\{1, 2\}$ of A. Then it is obvious that this relation is transitive but not connected for the number 3, which is in the set A, and does not stand in the relation R to any other element in A. To show that transitivity is independent of connectedness, that is, Axiom 1 for weak orders is independent of Axiom 2, it is sufficient to take the same set A as before, but now, the relation R is the set of the ordered pairs $\{(1, 2), (2, 3), (3, 1), (1, 1), (2, 2), (3, 3)\}$. Then it is clear that any two elements in the set A are connected by the relation R, but the relation R is not transitive, for, in order to be transitive, it must also have the pairs $(1, 3)$, $(2, 1)$, and $(3, 2)$.

The examples of independence given are trivial, but it is to be emphasized that it can often be a difficult task to establish whether or not an axiom is independent of the remaining axioms; that is, whether or not it can be derived from the remaining axioms. A very familiar mathematical example, with a long history in the twentieth century, is the proof that the axiom of choice is independent of the other standard axioms of set theory.

Padoa's Principle for Proving Independence of Primitive Concepts

Less familiar than proving the independence of axioms is the method of using models of a theory to prove independence of the primitive concepts of the theory. To prove that a particular primitive concept of a theory, for example, the notion of congruence in Euclidean geometry, is independent of the other primitive concepts, it is sufficient to find two models of the theory, such that the domain of both models is the same, the two models are the same for all the other primitive concepts of the theory, but the two models differ only in their realization of the concept in question. Thus, to prove congruence independence, what is required are two different models of the axiom in question, which are the same for all the other concepts, such as point, line, etc., but which have two distinct notions of congruence.

In the case of weak orders, Padoa's principle can be used in an obvious way to show that the concept of the binary relation is independent of the given set A. It suffices, for example, to use the two different orderings $\leq$, $\geq$ on the set of positive integers. On the other hand, since R is connected, the set A is definable in terms of the relation R for the special case of weak orderings by taking the union of the domain and range of the relation. But for different orderings, for example, partial orderings, which are reflexive, antisymmetric, and transitive on the set A, it is easy to show that the set A is an independent concept. Just let A in one model be a proper subset in the other, and elements in the relation come only from the first set.

Isomorphism of Models of a Theory

The separation of the purely set-theoretical characterization of the possible realizations of a theory from the axioms proper, which characterize models of a theory, is significant in defining certain important concepts. For example, the notion of two

models of a theory being isomorphic is often said to be axiom-free, since the definition of isomorphism of the models of a theory really depends on just the set-theoretical characterization of the possible realizations. A satisfactory general definition of isomorphism for the structures that are possible realizations of any sort of theory is difficult, if not impossible, to formulate. The usual practice is to formulate a special definition for the possible realizations of some particular theory. This is what will be done here, as already illustrated in the case of binary relations. A possible realization is a set-theoretical structure that is a nonempty set and a binary relation whose domain and range are included in that set. In this case the definition of isomorphism is as follows.

Definition 2 *A binary relation structure (A, R) is isomorphic to a binary relation structure (A', R') if, and only if, there is a function f such that*

1. *$D(f) = A$ and $R(f) = A'$*
2. *f is a one–one function*
3. *For a, b in A, aRb if and only if $f(a)R'f(b)$*

The definition of isomorphism for possible realizations of a theory is used to formulate a representation theorem, which has the following meaning. A certain class of structures or models of the axiomatized theory is distinguished for some intuitive or systematic reason and is shown to exemplify within isomorphism every other model of the theory. This means that, given any model of the theory, there exists in this distinguished class an isomorphic model. A good example of this can be found in the axiomatic theory of extensive measurement. Given any empirical structure that represents the data about subjective judgments of probability and satisfies the axioms of the theory, there is a numerical structure satisfying the axioms that is isomorphic to the empirical structure. Note, of course, that there is not any one single such isomorphism. Different individuals can have different empirical structures realizing their subjective probabilities, but there will be for each of them a particular numerical model of the axioms that is isomorphic to each given empirical structure.

Here is a simple and obvious, but useful, example of a representation result for two-person, zero-sum games that are finite. A game (X, Y, M), as introduced earlier, is finite just in case the sets X and Y are finite. Therefore, with the definition of isomorphism obvious from the result now to be stated, any finite game $G = (X, Y, M)$ with $X = (x_1, \ldots, x_m)$ and $Y = (y_1, \ldots, y_n)$ is isomorphic to the game $G' = (I_m, I_n, M')$, and $M'(i, j) = M(x_i, y_j)$, where the notation I_k denotes the set of positive integers $1, \ldots, k$. Therefore, any finite two-person zero-sum game may be represented by a game where X and Y are initial segments of the positive integers, even if vivid substantive descriptions of the individual strategies x_i and y_j have been given.

The use of the formal structure of games has been one of the most striking innovations in economic theory in the second half of the twentieth century, inspired above all by the publication in von Neumann and Morgenstern's (1944), *Theory of Games and Economic Behavior*. The formal isomorphism between many kinds of economic structures and games has been a surprisingly robust theoretical development. A recent elementary introduction to these ideas is Fudenberg and Levine (1988), and a more advanced text is Fundenberg and Tirole (1991).

Quantum Decision Theory

More recently than game theory, and much less well developed, is the introduction into psychology, as well as economics, of models with formal features isomorphic to those of quantum mechanics. It can be argued that the strange nonlocality to be found in quantum entanglement of distant particles is not relevant, but the contextuality, exhibited especially in quantum interference, is the important common feature (de Barros and Suppes, 2009). Applications, and further references, to the psychology of decision making are found in Busemeyer et al. (2006). Quite different applications are found in recent physics-inspired theories of financial markets, e.g., Baaquie (2004) and Haven (2002).

Invariance Theorems for Axiomatized Theories

In addition to having representation theorems for the models of a given axiomatized theory, it is also significant and useful to have explicit invariance theorems. The intuitive idea of invariance is most naturally explained in terms of either geometric theories or measurement theories.

Given a class of models, for example, analytical models in geometry and numerical models in measurement, with respect to which any other model of the theory can be represented, the invariance theorem is an expression of how unique the representation in terms of such an analytic model is. For example, in the case of the representation theorem for axiomatic formulations of Euclidean geometry, the invariance theorem states that any analytic model is unique only up to the group of Euclidean motions. This means that for any analytic representation of Euclidean geometry, any reflections, rotations, or translations of the analytic model will produce a new analytic model, also isomorphic to the set-theoretical model satisfying the qualitative synthetic axioms of Euclidean geometry. In fact, the most general theorem widens the scope to what is often called the group of generalized Euclidean transformations, namely, those that also permit a change in scale, so that no unit of measurement is fixed.

The situation is very similar in the case of theories of measurement. Given an empirical structure and a representing numerical model isomorphic to that structure, then, in the case of intensive quantities such as cardinal utility, for example, the numerical model is unique only up to the group of affine transformations, that is, transformations that multiply the unit of measurement by a positive real number and add a constant as well. This means that in fundamental measurement of a cardinal utility there is nothing but convention in the choice of a unit of measurement or a zero value.

Classical examples of important invariant theorems in physics are that structures of classical physics are invariant up to Galilean transformations, and in special relativity, invariant up to Lorenz transformations – in both these cases, further generalizations arise by also permitting changes in the units of measurement.

Theories with Standard Formalization

The set-theoretical framework for axiomatizing theories just discussed is used implicitly throughout the mathematical social sciences. Most of the axiomatic work that takes place in the social

sciences can be put in a straightforward way within the framework just described. On the other hand, there is a tighter framework for discussing the axiomatization of theories that leads to clarification of problems that arise in the conceptual or qualitative thinking about theories in the social sciences. The purpose of this section is to describe, in an informal way, this more narrowly defined framework and to give a sense of the kind of results that can be obtained. Most of the results are of a negative sort, important because they show what cannot be done by apparently very natural qualitative formulations of theories of preference, of subjective probability or related kinds of qualitative measurement, or scaling problems, especially in economics and psychology, and in anthropology, political science, and sociology.

A language with standard formalization is a language that is given a precise formulation within first-order logic. Such a logical framework can be characterized easily in an informal way. This is the logic that assumes

1. one kind of variable;
2. logical constants, mainly the sentential connectives such as *and*;
3. a notation for the universal and existential quantifiers; and
4. the identity symbol $=$.

A language formulated within such a logical framework is often called an elementary language. Ordinarily, three kinds of nonlogical constants occur in axiomatizing a theory in such a language – the relation symbols, also called predicates; the operation symbols; and the individual constants.

The grammatical expressions of the language are divided into terms and formulas, and recursive definitions of each are given. The simplest terms are variables or individual constants. New terms are built up by combining simpler terms with operation symbols in a recursive manner. Atomic formulas consist of a single predicate and the appropriate number of terms. Compound formulas are built up from atomic formulas by means of sentential connectives and quantifiers.

Possible realizations of elementary theories, i.e., theories formulated in an elementary language, assume an especially simple form. First, there is a nonempty domain for the structure. Second, corresponding to any relation symbol of the theory, there is a corresponding relation, including sets representing predicates as one-place relations. Corresponding to any operation symbols in the theory are operations defined on the domain of the structure, and, finally, individual objects of the domain correspond to the individual nonlogical constants of the theory. It is worth noting in passing that the definition of isomorphism for such elementary structures is straightforward and simple, which is not always the case for theories formulated in more complicated set-theoretical languages.

Some Positive Results about Axiomatizability

The first positive result uses two concepts. First, the set of all the finite models of a theory is called a finitary class of elementary structures. Second, a theory is recursively axiomatizable when there is an algorithm for deciding whether or not any formula of the language is an axiom of the theory in question.

Theorem 1 *Any finitary class of models of an elementary theory is axiomatizable, but not necessarily recursively axiomatizable.*

The importance of this result shows that the expressive power of elementary languages is adequate for finitary classes but not necessarily for the stating of a set of recursive axioms.

A more special positive result about finitary classes of models can also be given:

Theorem 2 *Let K be the finitary class of measurement structures with respect to an elementary language L and with respect to a numerical model R of L such that K includes all finite models of L homomorphically embeddable in R. If the domain, relations, functions, and constants of R are definable in elementary form in terms of* $(Re, \leq, +, \cdot, 0, 1)$ *then the set of sentences of L that are satisfied in every model of K is recursively axiomatizable.*

A universal sentence is one that has only universal quantifiers at the beginning with the scope of a quantifier the remainder of the sentence. In practice, such sentences are written as quantifier-free statements to simplify the notation. The axioms of weak ordering given earlier are of this kind. To be explicit, the conjunction of the two given axioms is a universal sentence, and this single universal sentence is, in this form, the single axiom for a weak ordering.

Theorem 3 (*Vaught's Criterion, 1954*). *Let L be an elementary language without function symbols. A finitary class K of measurement structures (with respect to L) is axiomatizable by a universal sentence iff K is closed under submodels and there is an integer n such that if any finite model M of L has the property that every submodel of M with no more than n elements is in K, then M is in K.*

The intuitive idea of Vaught's criterion for finitary classes of models of a theory is easy to explain. Consider again weak orderings. Because the axioms involve just three distinct variables, it is sufficient to check triples of objects in the domain of an empirical structure to determine if it is a model of the theory. Generally speaking, the number of distinct variables determines the size of the submodels that must be checked to see if universal axioms are satisfied. To have a universal axiom for a theory, or what is equivalent, a finite set of universal axioms, it is necessary that the number of distinct variables be some definite number, say n. By examining submodels involving no more than n objects, it is then sufficient to determine satisfaction of the axiom or axioms, and this is the intuitive idea of Vaught's criterion.

Some Negative Results About Axiomatizability

To begin with, it is useful to state as a theorem what is a corollary of Vaught's criterion. It is simply the negation of it for determining when a finitary class of models of a theory is not axiomatizable in an elementary language by a universal sentence.

Theorem 4 *Let L be an elementary language without function symbols and let K be a finitary class of measurement structures (with respect to L) closed under submodels. Then K is not axiomatizable by a universal sentence of L iff for every integer n there is a finite model M of L that has the property that every submodel with no more than n elements is in K, but M is not in K.*

It is natural to interpret the negative result stated in the general form here as showing that the complexity of relationships in finitary classes satisfying the hypotheses of the theorem

is unbounded, at least unbounded when the theory must be expressed by quantifier-free formulas of elementary logic.

The first application is something rather surprising. A semiorder is a structure $(A, \succ)$ satisfying the following three axioms.

Axiom 1 It is not the case that $(a \succ a)$.
Axiom 2 If $(a \succ b \,\&\, a' \succ b')$ then $(a \succ b' \vee a' \succ b)$.
Axiom 3 If $(a \succ b \,\&\, b \succ c)$ then $(a \succ d \vee d \succ c)$.

When the set A is finite, the following numerical representation holds:

$$\text{for every } a \text{ and } b \text{ in } A,\ a \succ b \text{ if and only if } f(a) > f(b) + 1.$$

What is now surprising is a result about the indistinguishability relation for semiorders, that is, the relation $\sim$ that is the negation of the characterization of the semiorder, namely, for a and b in A.

$$|f(a) - f(b)| \leq 1 \text{ iff } a \sim b.$$

The following theorem is from Roberts (1969).

Theorem 5 *Let L be the elementary language whose only nonlogical symbol is the binary relational symbol* $\sim$. *Then the finitary class J of measurement structures for the indistinguishability relation* $\sim$ *is not axiomatizable in L by a universal sentence.*

The next case of a negative result applying the negation of Vaught's criterion (Theorem 3) is the proof that the qualitative theory of utility differences or the qualitative theory, more generally, of various psychometric sensations is not axiomatizable by a universal sentence, contrary, of course, to the simple theory of order. This result is from Scott and Suppes (1958).

Consider the elementary language whose only symbol is the quaternary relation symbol 'D' with the intended numerical interpretation:

$$ab\ D\ cd \text{ iff } f(a) - f(b) \geq f(c) - f(d)$$

We then define the finitary class of measurement structures for algebraic difference as consisting of all models (A, D) such that

1. A is a nonempty finite set;
2. D is a quaternary relation on A; and
3. (A, D) is isomorphic to (A', Δ), where A' is a finite set of numbers and Δ is the quaternary numerical relation such that for real numbers x, y, u, and v, $xy\,\Delta\,uv$ iff $x - y \geq u - v$.

Theorem 6 *Let L be the elementary language whose only nonlogical symbol is the quaternary relation symbol D. The finitary class D of measurement structures for (algebraic) difference is not axiomatizable in L by a universal sentence.*

The intuitive idea of the proof can be seen from the construction of a 10-element structure, all of whose substructures have a numerical representation, but which does not itself have such a representation. The idea of this construction can then be generalized for arbitrary n in order to apply Theorem 4.

Using the same ideas, Titiev (1972) extended the results of Theorem 6 to additive conjoint measurement and to multidimensional scaling with the Euclidean metric. Titiev (1980) also gives a negative proof for the city block metric for $n \leq 3$ dimensions. Using more sophisticated logical results, it is possible to extend most of the results just stated to not being finitely axiomatizable. This means that existential quantifiers can be introduced, but the number of axioms must be finite in character. The main results here are those reported by Per Lindstrom, which together with the other results mentioned in this section are presented in detail in Luce et al. (1990).

Theorem 7 *The finitary class of measurement structures for algebraic difference is not finitely axiomatizable in the elementary language whose only nonlogical symbol is the quaternary relation symbol D.*

In a way, a still stronger negative result about axiomatizability can be proved for Archimedean axioms. Here is one standard formulation of such an axiom. If $a \geqslant b$ then for some n, $nb \geqslant a$, where nb is the combination of n copies of b. Notice that it is necessary to introduce a quantifier for integers not just for the empirical objects of the domain. Because the exact formulation of the negative result is rather complicated, the following informal theorem is given.

Theorem 8 *For any standard elementary language used to formulate a theory of measurement, there is no set of elementary formulas of the language equivalent to an Archimedean axiom for the theory.*

The best way to think about the Archimedean axiom in this context is that it is a second-order axiom and, therefore, cannot be formulated by an equivalent set of formulas, in first-order logic.

Still another way of looking at this result is that to characterize the real numbers we need some sort of second-order axiom such as Dedekind completeness, the Cauchy sequences, or the least-upper bound axiom, but none of these axioms, including the Archimedean axiom, can be formulated in a first-order language whose variables take real numbers as values. Narens (1974) provides a general account of Archimedean axioms in various forms.

For deeper and more general results on axiomatizability there is more recent work that can be cited, especially concerning the definability of linear orders for classes of finite models and the problem of the complexity of the class (Stolboushkin, 1992; Gurevich and Shelah, 1996; Hella et al., 1997).

Abstract

'Balance of power' in the relations between states can refer first to a situation in which the Great Powers – regional or global – possess roughly equal power resources. But the concept acquired a more specific meaning in the eighteenth century as a policy of Great Powers to prevent one of them from becoming the hegemonic power. This required that alliances between them should be geared to that purpose and thus be flexible. Balance of power policy was quite successful between reasonably satisfied dynastic states whose power resources were reasonably even. But the policy failed when that power balance suddenly became more uneven, as in the cases of Jacobin and Napoleonic France or the unification of Germany by Prussia. Balance of power policy developed further after the Congress of Vienna into the idea and practice of the 'Congress of Europe,' based on the premise of the common interest of the Great Powers in maintaining peace and stability. Because the Great Powers were rivals as well as allies, the 'Concert' idea could not prevent World War I. But it forms the basis of all later attempts to preserve or restore peace between states through collective security and international organization, such as the Concert of Europe, the League of Nations, and the United Nations.

The concept 'balance of power' can be confusing. It has two different, though interrelated, meanings. It can refer first to a situation in which the Great Powers of a particular figuration of states – whether regional or global – possess roughly equal power resources. A power equilibrium is unlikely; the differences must just be small enough to make the risk of going to war too high. To achieve hegemony or empire a highly uneven power balance is required.

A balance of power can be bilateral as well as multilateral. It was considered crucial in the hegemonial rivalry between the Soviet Union and the United States. The rivals saw arms competition as the primary indicator of the balance between them. However, by balance they in fact meant superiority. The unintended result was stalemate. The nuclear danger, at the time called a 'balance of terror,' chained them together and made 'superiority' meaningless.

Balance of power in the first sense thus refers to the state of the power balance between interdependent, rivaling states or their predecessors. The first theory about the power balances in competing kingdoms was probably formulated by Kautilya, around 450 BC in India. When states were first formed in Europe, their rivalry was guided by the maxims of 'reason of state.' But gradually their perception of common interests became stronger, as reflected in the development of diplomacy and international law and the creation of international organizations.

Balance of power in its second meaning was part of the process in which cooperation between Great Powers increased without removing their rivalry. It came to mean a policy to prevent a bid for hegemony of one of the Great Powers, by the threat of the other Great Powers allying against it. If deterrence of a hegemonist failed the alliance could become a war coalition to restore the balance. But the purpose of balance of power policy itself was to maintain the status quo. To succeed, the power differentials between the Great Powers should remain small enough to foreclose hegemonic aspirations. The first meaning of balance of power was therefore a condition for the second.

Background

How and why did balance of power policy emerge? The European peace conference at Westphalia in 1648 to end the many conflicts comprising the Thirty- and Eighty-Years (Dutch independence) Wars was not yet a joint attempt to develop a more stable balance of power in Europe. But the conference brought the representatives of the hitherto separate northern and western power balances together. Though the participating states in Europe recognized one another as such by treaty, repudiating the prior claims to supreme authority of empire and church, dynastic rivalry remained. As Wedgwood remarked about the long delay of actual negotiations in Munster: "The ruling powers … asked for peace always in a general sense: when it came to practical action they were always prepared to fight for a little longer in order to gain their own particular end" (Wedgwood, 1963: p. 474). The peace conference became possible after expansionist ends could no longer be reached. Popular sentiment against war, very strong in the devastated German lands, did not make much difference, however. War in the dynastic period was characterized by Kant as a 'pleasure

party' for princes, who themselves did not suffer from them as the people did. For durable peace, dynastic states should be replaced by republics, by their nature responsive to the people, and willing to form a commonwealth together. Indeed, when the power distribution between dynastic states was still fluid and difficult to assess as in the sixteenth and seventeenth centuries, wars were frequent.

The peace of Westphalia simultaneously ended a plurality of conflicts. It made France more powerful and reduced Habsburg power. It also contributed to the rise of new Great Powers like Russia and Prussia and to the fall of Spain, Sweden, and later the Netherlands. One European power balance came into being. The monopolization processes that had led to the forming of dynastic states out of feudal fragmentation continued in the rise of Great Powers.

In the larger dynastic states, the increase of the king's power and authority had to be at the expense of other centers of power, such as the warrior nobility and autonomous towns. The domestic consolidation of dynastic regimes made stability in interstate relations more desirable. Balance of power policy came in useful. But it was precarious. Power resources changed all the time, so attempts at acquiring hegemony and war between Great Powers could not be excluded.

The Classical Balance of Power in Europe

Balance of power policy was practiced before it became an explicit principle. The power of Louis XIV's France grew to such an extent after the Peace of Westphalia that the other European powers feared it might acquire hegemony. A French attempt to use the Spanish succession to increase its power aroused Britain into forming in 1701 in The Hague an alliance of the other Great Powers against France. This coalition won the war and the Treaty of Utrecht of 1713 considerably reduced the power of France. That treaty also readjusted power relations all over Europe, and France lost some colonies to Britain. But it followed the prescription of balance of power policy that one's adversaries should not be destroyed, as that would upset the power balance between the allies.

In the eighteenth century five Great Powers emerged that would remain until 1914. They included one global and colonial sea power (Britain), two continental powers (Prussia and Austria), one power with both continental and maritime colonial ambitions (France), and an imperial power, with its territory stretching beyond Europe (Russia). Though the Ottoman Empire was in practice part of the European power balance, it was not a member of the quintet. Though the power resources of the five Great Powers were quite different, they were not too widely divergent most of the time to make balance of power policy impossible.

What exactly was classical balance of power policy? As the pamphlet, *Europe's Catechism* (1741) defines it:

> The Balance of Power is such an equal Distribution of Power among the Princes of Europe, as makes it impracticable for the one to disturb the Repose of the other … It may be destroyed by Force or Fraud, by the Pusillanimity of some, and the Corruption of all … When any Potentate hath arrived to an exorbitant share of power, the Rest (ought) to league together and reduce him to his due Share of it. Otherwise there is but one Potentate, and the others are only a kind of Vassals.

The *Catechism* shows that balance of power policy was well understood at the time. It clearly describes its functions: to prevent hegemony includes maintaining the 'Repose' of the participating powers, implying that they were no longer interested in expansionist adventures and had become status quo powers.

Balance of power policy requires that the Great Powers are able and willing to shift their alliances to deter hegemonic aspirations. That goal can be supported by a balancer. Britain, as a global sea power, could fulfill this role by always aligning itself against the leading power on the continent.

In the long run, however, balance of power policy can only be successful if the power balance between the Great Powers does not change too drastically. It still allows for cooperative expansion, as the three divisions of Poland among Russia, Austria, and Prussia in the late eighteenth century make clear. Conquest of Poland by one of them would have disturbed the balance of power.

The Congress of Vienna and the Concert of Europe

Balance of power policy did not always deter all Great Powers. Revolutionary France no longer respected the dynastic order in Europe. First, the Jacobin regime and then Napoleon set out on conquest, supported by the new power of popular conscript and volunteer armies, motivated by nationalism. Then balance of power policy had to change into a war coalition to undo the conquests of the hegemonist and restore the balance. As France occupied most of the continent, this took time. The decisive turn in the war came when Napoleon overextended his power and failed to subdue Russia.

The main members of the war coalition (Russia, Britain, Prussia, and Austria) expressed their war aims as the restoration of a just balance of power and a redivision of their respective forces suitable to assure this equilibrium. The Congress of Vienna followed the rules of balance of power policy: France was readmitted as one of the Great Powers and as member of the conference. As part of the postwar power balance the newly created Kingdom of the Netherlands – being in between Britain, France, and Prussia – was strengthened by the inclusion of the Southern Netherlands in the Kingdom.

With 'A World Restored' (Kissinger, 1957) in Vienna, a relatively stable period began again. No great war occurred until 1914. Still, in the nineteenth century maintaining the balance went together with more intense competition, whether for military and industrial power resources or for colonial possessions. There were few wars between a limited number of Great Powers, such as the Crimean War. Yet, rulers recognized a common interest in preserving a European balance of power.

The Concert of Europe and Its Global Successors

Balance of power policy was extended at the Conference of Vienna by the balancer Britain. In 1815 its Foreign Secretary Castlereagh drafted Article VI of the Quadruple Alliance Treaty

(to which France later acceded), which provided for periodic meetings between the Great Powers: "for the consideration of the measures which shall be considered the most salutary for the repose and prosperity of nations and the peace of Europe" (Kissinger, 1957: p. 186).

This 'conference system' broke down in 1822 when Castlereagh's successor Canning refused to support France's proposal for joint armed intervention in Spain. But the idea of a Concert of Europe to prevent and solve conflicts did not disappear. In 1855, Austria called a conference to prevent a war between Russia and Turkey. But it failed and the Crimean War broke out. That was ended by the Conference of Paris (1856), at which the British Foreign Secretary Lord Clarendon tried to strengthen the role of conference diplomacy by proposing the rule that states would seek 'good offices' before going to war. Two other important conferences were held in Berlin (1878 and 1884–85), both at the initiative of Bismarck. In the first, he acted with success as 'honest broker' between Russia, Britain, Austria–Hungary, and the Ottoman Empire to settle conflicts over the Balkan and in the Near East, resulting from the decline of the Ottoman Empire. The most important result of the second was that the Great Powers agreed to give control over the Congo to King Leopold of Belgium. As with the Netherlands in 1815, balance of power policy required that the Congo would not be controlled by one of the Great Powers, no matter what that would mean for the Congo itself.

The idea of a Concert of Europe went further than balance of power policy. It could imply collective Great Power domination. But it could not prevent a second complete breakdown of the balance of power. The rivalry for colonial possessions, symbolized by the scramble for Africa, became closed toward the end of the century. The world had been divided. Latecomers, such as Germany and Italy could not be satisfied. At the same time, the power balance in Europe became more uneven. After three wars, (with successively Denmark, Austria, and France) Prussia made itself the nucleus of a powerful new German Empire. Its first Chancellor Bismarck still thought in terms the balance of power. But after he left in 1890, Emperor William II began to harbor hegemonic ambitions. The other Great Powers did not form an antihegemonic alliance against Germany's aspirations and growing capability. On the contrary, Austria–Hungary sided with Germany, whereas Britain, France, and Russia formed a Triple Alliance. Two inflexible alliances stood against each other. Czar Nicholas' attempt to revive the conference idea in the form of general peace conferences, held in The Hague in 1899 and 1907, was not successful. The outbreak of World War I in July 1914 demonstrated again that balance of power policy was precarious.

Still, the winning alliance of World War I depended on the balancing effect of the entry of the United States. But restoring a balance of power was not a stated purpose of the postwar conference of Versailles. President Wilson believed that balance of power policy was responsible for the continual scourge of war in Europe. He looked for a lasting basis for peaceful conduct of states in collective security and national self-determination. Collective security was based on all members of the League of Nations uniting against an aggressor. But it proved impotent even against Italy, itself not a Great Power. Wilson's critical attitude toward balance of power policy was representative of the idealist thinking about international politics that was influential after the horrors of World War I. After the even worse horrors of World War II its counterpart realism, stressing the importance of power and military preparedness, became dominant again.

In the Security Council of the UN, the idea of a Concert of Great Powers became institutionalized. American President Roosevelt, who had again balanced the hegemony of Germany and its allies, saw the role of Great Powers in the Security Council as 'international sheriffs.' But a permanent Conference embodied in an international organization could not solve the problem of Great Power competition either. Hegemonic rivalry started again after a few years between the United States and the Soviet Union, thereby paralyzing the Security Council. Their rivalry did not lead to another great war primarily because of the consequences of the shared danger of a nuclear war. After the peaceful end of the hegemonic rivalry and of the Soviet Union, consensus for a time reigned in the Security Council, making a mandate for the use of force against Iraq possible. But China abstained. Rivalry again sets the tone in the Security Council.

Development beyond balance of power policy has thus not come very far. It has not been replaced by international organization. The dynamic of rivalry between states and especially Great Powers has not fundamentally changed, even though their domestic development now requires more cooperation.

Balance of Power in Other Parts of the World

Power balances have been part of the development of state systems everywhere, so have wars as part of hegemonic struggles. Thinkers about interstate relations, such as Kautilya in India or the Legalists in the China of the Warring States were, like Machiavelli, advisors to princes, primarily interested in increasing the power of their own state rather than in a balance of power. That was also the case with dynastic states in Europe. But in Europe balance of power policy replaced reason of state as the dominant policy orientation. Why? The explanation may be found:

1. in the relatively even Great Power balance that developed at the end of the seventeenth century;
2. in the importance of 'Repose' for dynastic regimes;
3. in colonial expansion (and Russia's frontier in Asia) as a substitute for territorial expansion within Europe; and
4. in the increasing repugnance for war in established states, though in the nineteenth century it could be replaced by nationalism.

The European balance of power became global in the twentieth century. The bipolar balance between the two remaining Great Powers after 1945 was perceived by both as covering the world as a whole. The smallest power advantage obtained by the one had to be compensated by the other.

In the post-Cold War world regional balances became more important. In Southeast Asia, for example, the members of the Association of Southeast Asian Nations (ASEAN) had transformed their economic cooperation in a security alliance directed to what they saw as the hegemonic ambitions of Vietnam, demonstrated by Vietnam's intervention and occupation of Cambodia. Recently Vietnam joined the ASEAN

because of an unspoken common interest in balancing China's possible bid for hegemony in the region. American foreign policy has been constantly concerned with regional balances of power, in Europe, but also in East Asia and the Middle East.

Conclusion: A Permanent Feature of International Politics?

Since the Congress of Vienna all attempts to create an international order were based on an extension of balance of power policy. The exception was the League of Nations. But its impotence can be explained by the neglect of balance of power considerations and overestimation of the effectiveness of the all against one requirement of punishing an aggressor, especially if that were a Great Power.

After 1991, the United States was the only global Great Power left. It is not likely that it will remain so indefinitely. Potential challengers, such as China or the European Union or the reformed Russia, are already there, even though still relatively weak. Will balance of power policy become relevant again in the future? As long as a monopoly of violence at the international level does not come into being, balance of power policy may well remain relevant.

Abstract

Developmental psychologist Paul B. Baltes (1939–2006) was born in Saarlouis, Germany. After studying in Germany he moved to the United States, where he continued the conceptual and methodological quest of his doctoral dissertation to transform developmental psychology into a science that seeks to describe, explain, and modify individual differences in behavioral development across the entire life span. His work was pivotal in establishing life span psychology as a comprehensive and distinct theoretical orientation within contemporary developmental psychology. Paul Baltes' career was characterized by internationality, interdisciplinarity, generativity, societal concern, and institutional prudence and sagacity. One of his central research interests was to explore age-graded changes in the range of plasticity in individual development, with the goal to identify and promote personal and societal conditions that favor successful aging. At the same time, he was not negligent of the negative sides of very old age, and spoke of old age and aging as 'hope with a mourning band.'

Life

Paul B. Baltes was born in 1939 in Saarlouis, Germany. Between 1959 and 1963, he studied psychology at the University of Saarland in Saarbrücken with Ernst E. Boesch, who was a student of Swiss psychologist Jean Piaget, and Günther Reinert, who would remain his academic mentor for many years. As Baltes himself noted, "Piagetian developmental cognitive structuralism and Boeschean cultural-psychological theory thus were two of the cornerstones in my study of psychology. The third, provided by the guidance of Günther Reinert, was psychometrics and the developmental study of intelligence" (Baltes, 2000: 11).

During that time he met Margret M. Labouvie who later became his wife and close collaborator. After obtaining his master's degree in psychology on the differentiation hypothesis of intelligence in childhood (Reinert et al., 1965), he and his newlywed wife Margret spent a year at the University of Nebraska. As a young graduate exchange student Paul Baltes collaborated with the eminent developmental psychologist and gerontologist K. Warner Schaie. Back in Saarbrücken, he continued his work on the basic methodological problem of disentangling age from cohort and period effects when studying development, and completed his dissertation on this topic in 1967 (Baltes, 1968; now a 'citation classic'). He then accepted K. Warner Schaie's offer of an assistant professorship at the University of West Virginia.

The first West Virginia conference on life span development (Goulet and Baltes, 1970) marks the emergence of life span psychology as a meta-theoretical framework within modern psychology (cf. Tetens, 1777; Thomae, 1959). It formed the basis of what later became the classic series, "Lifespan Development and Behavior," edited by Paul Baltes in collaboration with social psychologist Orville Gilbert Brim Jr., and later with sociologist David Featherman and developmental psychologist Richard M. Lerner. In this series, a continually growing group of scholars radically criticized the dominant interpretation of developmental psychology as a science primarily oriented toward childhood and biology-based growth processes. According to this critique, development includes the whole life span from conception into old age (Baltes and Goulet, 1970) and comprises losses as well as gains, maturation as well as senescence, and biological as well as cultural influences. Paul Baltes was one of the pioneers of this theoretical orientation in modern developmental psychology, as first described in the article on the life span perspective on human development that was published in 1980 in the *Annual Review of Psychology* (Baltes et al., 1980).

At the age of 33 years Paul Baltes was appointed head of the Division of Individual and Family Studies at the College of Human Development of Pennsylvania State University, where he set up an interdisciplinary graduate program on research questions of lifelong development – together with colleagues such as John R. Nesselroade and Richard M. Lerner. In 1980, the Max Planck Society recruited Paul Baltes back to Germany as Director at the Max Planck Institute for Human Development in Berlin. A quarter of a century later, when he reached emeritus status, life span thinking had become integrated into developmental psychology in both North America and Germany. In the late 1990s he took up the challenge of coediting the first edition of the *International Encyclopedia of the Social and Behavioral Sciences* together with Neil J. Smelser. Its forerunner was the *International Encyclopedia of Social Sciences* edited by David Sills in 1968. As coeditor-in-chief, Paul Baltes ensured that fields such as behavioral and cognitive neuroscience, genetics, evolutionary sciences, law, psychiatry, and, of course, developmental psychology were represented in the 26-volume work that was published in 2001 (Smelser and Baltes, 2001).

In 1999, Margret Baltes, his longtime collaborator, companion, and mother of their two children, died suddenly. Christine Windbichler, Professor of Law at Humboldt-Universität zu Berlin, later became his second wife.

Taking on the title of Director Emeritus in 2004 was only a transition to new challenges for Paul Baltes. He was appointed Distinguished Professor at the University of Virginia and Director of the Max Planck International Research Network on Aging (MaxnetAging), the first virtual Max Planck Institute that was geared toward the multidisciplinary investigation of

human aging. Furthermore, until the very end of his life, he was the Chair of the International Max Planck Research School on the Life Course (LIFE) and a board member of the working group 'Opportunities and Problems of an Aging Society: The World of Working and Lifelong Learning' launched by the German National Academy of Sciences Leopoldina and the German National Academy of Science and Engineering (acatech). Sadly, his own life was cut short by cancer and he died in Berlin aged 67 in 2006.

Honors

Paul Baltes left an oeuvre of more than 300 publications including 27 books, and the 26 volumes of the *International Encyclopedia of the Social and Behavioral Sciences*. His scientific recognition is also reflected in the honorary degrees that he received as well as countless memberships in national and international academies. For his scientific work, he received 12 prestigious prizes and awards from national and international professional societies. He was a foreign member of the American Academy of Arts and Sciences and the Royal Swedish Academy of Sciences. Honorary doctorates were bestowed on Paul Baltes by the Universities of Jvyäskylä, Stockholm, Geneva, and Humboldt-Universität zu Berlin. His international awards included the American Psychological Association's Award for Distinguished Contributions to the International Advancement of Psychology, the Robert W. Kleemeier Award in Recognition of Outstanding Research from the Gerontological Society of America, and the Novartis Prize for Gerontological Research awarded by the International Association of Gerontology. Paul Baltes also received highest recognition beyond the scientific community. He was the only psychologist to be awarded membership in the German Order 'Pour le Mérite' for the Arts and Sciences, and received the Federal Republic of Germany's Great Cross of Merit with Star.

Profile as Scientist and Scholar

Beyond scientific productivity and professional as well as public honors, Paul Baltes as a person and his role in science and society may be best characterized by five qualities: internationality, interdisciplinarity, generativity, societal concern, and institutional prudence and sagacity (see also Staudinger, 2007).

Internationality

Throughout his career, Paul Baltes built bridges and developed international networks. He firmly believed that international exchange increases the quality of scientific work and promotes scientific insights. Only very few German scientists have reached equally high recognition in the USA. Good examples of such networks are the network of life span researchers as captured in the Lifespan series, MaxnetAging, and the international doctoral program LIFE, which continues to flourish to the present day.

Interdisciplinarity

As spiritus rector of life span psychology, Paul Baltes was committed to the interdisciplinary study of human development. During his time as department head at Penn State, he shepherded an interdisciplinary faculty composed of psychologists and sociologists. His work for the Social Science Research Council and the European Research Foundation also provided rich experiences in interdisciplinary exchange. He initiated the Berlin Aging Study (BASE), connecting biomedical and psychological with sociological and economic perspectives on aging. BASE also became a success because Paul Baltes managed to lead the various disciplinary directions to an equal dialogue (Baltes and Mayer, 1999). During his later years, he took great pleasure and pride in developing discourses that transcended disciplinary horizons in the context of the academies of which he was a member, particularly in the Order 'Pour le Mérite' for the Arts and Sciences. He linked his striving for the Renaissance ideal of a comprehensively informed scholar with a wakeful eye for the necessities and opportunities of modern societies.

Generativity

Early on and throughout his career, Paul Baltes's work was characterized by generativity. According to Erik Erikson, caring for the following generations, passing on insights and experiences, is the central developmental challenge of the middle and later years. Paul Baltes took on this challenge much ahead of time. He mentored his doctoral students and postdoctoral fellows with a great deal of personal investment in many areas of life. In the 1980s, soon after his return to Germany, Paul Baltes and other developmental psychologists launched the first graduate fellowship program in Germany funded by the Volkswagen Foundation, which later became a model for graduate programs in Germany funded by the German Research Foundation (DFG). Among the cherished projects of his later years were the foundation of the International Max Planck Research School LIFE (see http://www.imprs-life.mpg.de) and the establishment of an academy of sciences for young academics. The latter project, the 'Junge Akademie,' was implemented as a collaboration project between the Berlin–Brandenburg Academy of Sciences and Humanities and the German National Academy of Sciences Leopoldina (of which Paul Baltes was vice-president). The 'Junge Akademie' has since become a role model and example for similar initiatives in many other countries.

Societal Interest

Paul Baltes displayed concern for societal issues. He firmly believed that psychology has something to say and even more strongly, that it can contribute to the solution of challenges that modern societies are facing. Going public as a scientist is an art that requires great care and investment. Paul Baltes excelled in this regard as well. He advanced and influenced societal discussions about lifelong learning, demographic aging, the chances and hardships of old and very old age, and the question of self-determined death.

Institutional Initiative and Prudence

Science takes place within institutions and is influenced by institutional characteristics and their logic. Paul Baltes thought and acted in the interest of the institution and thereby contributed to the flourishing of the Max Planck Institute for Human Development in Berlin. Over the years,

he also took on many responsibilities to promote the standing of the behavioral and social sciences within the Max Planck Society, and took a leading role in numerous networks promoting the study of adult development and aging from a life span perspective.

Contributions to the Behavioral and Social Sciences

Paul Baltes' doctoral dissertation on cohort effects marked the starting point for a comprehensive methodological and conceptual oeuvre (e.g., Baltes, 1968; see also Schaie, 1965). Paul Baltes formulated the scientific tenets and rationale of life span psychology (Baltes et al., 1977; Baltes, 1987; Baltes et al., 2006a). His conceptual and methodological writings have become milestones in the scientific study of behavioral development.

Quite early, Paul Baltes developed interest in the malleability of cognitive functioning in adulthood and old age. His work on cognitive training demonstrated the continued existence of learning potential in adulthood, and foreshadowed much of the recent interest in this topic. Together with Reinhold Kliegl, he introduced the testing-the-limits paradigm to delineate age differences in memory performance after instruction and training in mnemonic skill (Baltes and Kliegl, 1992). Later his interest in cognitive plasticity expanded to include personality functioning and to link the notion of plasticity with traditional conceptions of resilience across the life span (Staudinger et al., 1995). Together with Ursula Staudinger and Jacqui Smith, he succeeded in establishing a measurement model of wisdom, defined as high levels of expertise about the fundamental pragmatics of life, and identified the constellation of personal attributes and social opportunities that are germane to its emergence (Baltes and Staudinger, 2000). Together with Ellen Skinner, he refined the study of control beliefs in childhood by introducing the tripartite conceptualization of control, agency, and means–ends beliefs (Skinner et al., 1988), in line with his emphasis on goal-directed action as a central concept in developmental theory.

In the late 1980s, Paul Baltes initiated and launched the Berlin Aging Study (Baltes and Mayer, 1999), a multidisciplinary, longitudinal study on old age and aging. The coprincipal investigators were Hanfried Helmchen, a psychiatrist, Karl Ulrich Mayer, a life-course sociologist and codirector at the MPI for Human Development, and Elisabeth Steinhagen-Thiessen, a geriatrician. Among the key features of the Berlin Aging Study are a truly multidisciplinary approach, expressing Paul Baltes's conviction that progress in science requires a dialogue among equals in which no discipline dominates the other; a focus on very old age (Gerstorf et al., 2013); and a strong interest in methodological issues such as sample selectivity (Lindenberger et al., 2002).

Besides the continued potential for growth, Paul Baltes was also interested in the reasons for decline in adulthood and old age. He showed that hearing, seeing, and walking require increasing cognitive resources with advancing adult age (Lindenberger and Baltes, 1994). Later, he advocated linking research on behavioral development to research on neural mechanisms. In this context, he promoted the notion of 'bio-cultural co-constructivism' and warned against regarding behavior as the dependent variable of the brain (Baltes et al., 2006b).

Together with his first wife Margret, Paul Baltes was interested in the orchestration of psychological mechanisms promoting successful human development. Together they introduced the selection, optimization, compensation (SOC) model of developmental regulation, which posits the three mechanisms as regulatory mechanisms of human development (Baltes and Baltes, 1990; Freund and Baltes, 1998). The SOC model has been integrated into systems theory (Boker, 2013), and successfully applied to the study of specific developmental tasks, such as the resolution of work–family conflict (e.g., B. Baltes and Heydens-Gahir, 2003).

Paul Baltes has left a rich legacy. His work continues to inspire research in developmental psychology and gerontology. After his first wife's death in 1999, Paul Baltes established the Margret M. Baltes Foundation to promote their common goal of advancing life span developmental and gerontological research. Upon his own death in 2006, it was renamed the Margret M. and Paul B. Baltes Foundation. According to its website, "The Margret M. and Paul B. Baltes Foundation aims to advance research in developmental psychology and gerontology and to underline its relevance in science and society. It encourages researchers to dedicate projects and careers to these fields and to widen the empirical and theoretical understanding of humans and society in adulthood and old age. It aims to highlight societal initiatives that point to the relevance of such research."

Paul Baltes was a master at forging links – in the academic, science management, societal, and personal world. Therefore, his activities, his knowledge, and worldwide recognition were not restricted to his home discipline, developmental psychology; they drew wide circles into the humanities and natural sciences. He put questions into the open and made them the starting point of a new research idea, a new institution, or a new collaboration. Paul Baltes was able to establish developmental psychology as an equal partner among disciplines. In accordance with his theory of the permanent incompleteness of human nature (Baltes, 1997), his scientific work was not finished and will never be finished.

Abstract

Bankruptcy is a legal process that generally seeks to effectuate two goals: (1) an orderly distribution of a debtor's pre-bankruptcy assets and/or future income for the benefit of creditors and (2) financial rehabilitation of the debtor. The first goal can be viewed as the law's response to the common-pool problem that arises when a debtor has insufficient resources to repay creditor claims. The second goal can be viewed as the law's response to alleviating the financial distress that renders a debtor economically unproductive.

Bankruptcy is a legal process that generally seeks to effectuate two goals: (1) an orderly distribution of a debtor's pre-bankruptcy assets and/or future income for the benefit of creditors and (2) financial rehabilitation of the debtor. The first goal can be viewed as the law's response to the common-pool problem that arises when a debtor has insufficient resources to repay creditor claims. The second goal can be viewed as the law's response to alleviating the financial distress that renders a debtor economically unproductive – that is, when the debt burden becomes so great that it interferes with the debtor's ability to make future financial commitments. These two goals provide a metric against which the content of bankruptcy law can be evaluated for its soundness.

Bankruptcy's Equality Principle

When a debtor ceases to repay his or her debts voluntarily, creditors must seek through other means to collect the debts owed to them by the debtor. Some creditors might have had an opportunity prior to the debtor's default to contractually create an interest in property of the debtor to secure repayment of the debt (i.e., a consensual lien). Other creditors might not have had such an opportunity. Instead, they would have to rely on the creation of an involuntary lien – whether arising solely by operation of law under certain circumstances or upon the occurrence of certain conditions (i.e., a statutory lien), or whether obtained through judicial process (i.e., a judicial lien) – on the debtor's property to secure repayment of the debt. The property to which the lien, whether consensual or nonconsensual, has attached will serve as a source of repayment. The creditor will apply the proceeds obtained through liquidation of such property to reduce the outstanding amount of the obligation owed to it by the debtor.

When a debtor has insufficient resources (i.e., assets and income) to repay his or her creditors in full, a common-pool problem arises. This problem is exacerbated by the distributive principle that generally governs nonbankruptcy collection remedies – that is, "first in time, first in right". Put another way, the creditor who is first to take the necessary steps to establish legal entitlement to satisfaction of the debt from a particular asset of the debtor will have priority over subsequent creditors who make a claim to the same asset. This legal rule prompts a race of diligence among creditors to dismantle the failing debtor. Each creditor will seek to establish legal entitlement to the debtor's assets in order to assure itself of repayment to the fullest extent possible. Because there are insufficient resources to pay all creditors in full, there will be winners (e.g., those who are fully paid) and losers (e.g., those who do not receive any payment). Moreover, the competition for resources may result in a disorderly, inefficient allocation that does not maximize their value, thereby harming the group as a whole. In other words, the individualistic nature of competition for a debtor's resources will likely prompt creditors to pursue their non-bankruptcy remedies against the debtor in a way that promotes the creditor's self-interest to the detriment of the creditor group.

Bankruptcy seeks to overcome the common-pool problem by effectuating a shift to a compulsory collective proceeding pursuant to which the debtor's assets and/or future income will be administered for the benefit of all creditors (Jackson, 1986: pp. 7–19). The initiation of a bankruptcy proceeding generally creates an estate that includes the debtor's prebankruptcy property and simultaneously enjoins the pursuit of individual remedies by creditors against the debtor and its property. The grant of jurisdiction over the bankruptcy case and the debtor's property enables the court or agency that administers the process to conduct a uniform proceeding in a single forum, sorting out creditors' claims against the debtor and its property.

Instead of providing the same treatment for all creditors, bankruptcy focuses on organizing creditors into various classes based on their nonbankruptcy entitlements. Once those classes have been established, bankruptcy law concerns itself with providing equal treatment *within*, rather than *across*, creditor classes. Because of this, the law allows for certain creditor classes (e.g., secured creditors) to receive more favorable treatment than others (e.g., unsecured creditors). Thus, the process of marshaling and distributing a debtor's resources in bankruptcy is oriented pursuant to the principle of equal treatment of *similarly situated* creditors (the "equality principle").

Bankruptcy's Fresh-Start Principle

To ameliorate a debtor's financial distress, bankruptcy law's primary substantive relief is the discharge, which generally

releases the debtor from personal liability on prebankruptcy debts. Such relief provides the debtor with a fresh start and represents societal consensus to forgive a debtor's financial obligations. Two animating issues underlie such substantive relief: (1) the type of debtor that should be eligible for that relief and (2) the scope of such relief. The former issue turns on normative judgments about when a debtor may seek respite from financial failure under the protective cover of bankruptcy law, whereas the latter issue addresses the extent of relief to be conferred upon debtors who are deemed eligible for it.

Eligibility rules for bankruptcy may focus on a variety of characteristics, such as the organizational structure of the entity seeking bankruptcy relief (e.g., in the United States, domestic insurance companies are not eligible to file for bankruptcy) or the debtor's motivation for seeking bankruptcy relief (e.g., eligibility may be denied based on the debtor's bad faith in seeking relief). On the other hand, defining the scope of bankruptcy relief necessarily entails judgments about the debtor's fresh start. Limits on such relief are generally imposed in one of two forms: (1) the price of discharge and (2) the amount of debt discharged. With respect to the former, the law generally requires a debtor to relinquish either all of its prebankruptcy assets and/or a portion of its future income. With respect to the latter, the discharge may not extend to cover all prebankruptcy debts (e.g., certain tax debts). Accordingly, one might conceive of the benefit of discharge as the extent to which the amount of debt forgiven exceeds the price paid for the discharge.

The Content of Bankruptcy Law

In analyzing bankruptcy law, one can generally point to the equality and fresh-start principles as influencing its content. Put another way, bankruptcy law might be viewed as an operative framework for effectuating these principles. While some of the legal rules may apply across all classes of bankruptcy cases – that is, cases involving both natural persons and legal entities, such as corporations – others may apply only within certain classes.

Implementing the Equality Principle

As previously mentioned, the fresh-start principle generally requires the debtor to pay a price for the discharge of debt – namely, relinquishment of all prebankruptcy assets and/or a portion of the debtor's future income. The price exacted from the debtor will dictate the amount repaid to creditors. Because debtors generally face a choice of seeking relief either through liquidation (i.e., converting their prebankruptcy assets into proceeds for distribution to creditors) or reorganization/rehabilitation (i.e., relying on future income to repay creditors, but nonetheless preserving the option of using prebankruptcy assets for repayment), the law must devise a baseline for the repayment of creditor claims.

The repayment baseline generally focuses on the amount that creditors would receive on account of their claims if the debtor's prebankruptcy assets were liquidated and distributed to creditors. Establishing this baseline requires legal rules specifying: (1) the property available for liquidation, (2) the amount of creditor claims, and (3) the order and manner in which such claims will receive payment. Importantly, as the scope of the property available for liquidation (i.e., the price of discharge) broadens, the net benefit of discharge theoretically decreases. In other words, the more property a debtor must relinquish in exchange for the discharge, the less robust the discharge becomes. Accordingly, the fresh-start principle is very much implicated in defining the scope of property available for liquidation.

Once the law has identified the property that should be available for liquidation, the focus shifts to identifying the types of claims that can be made by creditors against such property. This process necessarily entails defining what constitutes a claim and then establishing a framework for determining the allowance or disallowance of such claims against the debtor's estate. Bankruptcy law generally strives to provide a comprehensive, all-encompassing definition of a claim. For example, the US Bankruptcy Code broadly defines a claim as a "right to payment, whether or not such right is reduced to judgment, liquidated, unliquidated, fixed, contingent, matured, unmatured, disputed, undisputed, legal, equitable, secured or unsecured" (U.S. Code, 2012: Vol. 11, sec. 101(5)(A)) and imposes the temporal limitation that the claim should have existed as of or prior to the commencement of the debtor's bankruptcy case. Such an approach has the effect of consolidating all of the debtor's prebankruptcy liabilities for resolution *en masse* in the bankruptcy case – an instrumental step for effectuating the shift from individualistic creditor remedies outside of bankruptcy to a collective proceeding seeking to redistribute the debtor's limited resources for the benefit of all creditors.

Importantly, bankruptcy law generally defers to nonbankruptcy law for purposes of determining which substantive entitlements constitute a right to payment giving rise to a claim. Were bankruptcy law to do otherwise, the possibility arises that some creditors would receive more favorable treatment in bankruptcy rather than outside of bankruptcy – that is, in those instances where bankruptcy law would provide a more robust substantive entitlement than nonbankruptcy law. This, in turn, would prompt forum shopping by creditors who would receive preferred status within bankruptcy, thereby creating an opportunity for self-interested behavior (e.g., the preferred creditors attempting to push the insolvent debtor into an involuntary bankruptcy proceeding) that undermines the collective interests of the group of creditors as a whole. In other words, bankruptcy law would perpetuate the problem that it attempts to solve (Jackson, 1986: pp. 25–27).

The claim allowance process determines who may receive payment from the debtor's estate. Establishing the validity and the amount of the claim is at the heart of this process. In the context of the common-pool problem, reductions in the number and amount of claims are likely to produce a greater return to the remaining claimants in the proceeding. The possibility of claim disallowance thus provides an opportunity for creditors to knock out competing claimants from the competition for the debtor's limited resources. Of course, in many instances, this outcome may only have marginal benefit because of the *pro rata* approach to distributing the debtor's resources in bankruptcy (as discussed below) and because of the costs incurred in establishing the grounds justifying the

disallowance of a claim. Given these dynamics, pragmatism dictates an overinclusive approach toward the allowance of claims. In the United States, for example, the law presumes the validity and amount of claims and narrows the set of circumstances under which a claim will be disallowed. By adopting an allowance approach that complements the broad definition of a claim for bankruptcy purposes, bankruptcy law evinces hostility toward claim litigation and instead aims to facilitate an expeditious and efficient resolution of creditor claims (Pardo and Lacey, 2009: pp. 186–187).

Once the identity of claimants entitled to receive distributions from the debtors' estate has been established, bankruptcy law shifts its attention to the order of such distributions. For a creditor fortunate enough to have created a prebankruptcy lien in property of the debtor to secure repayment of the debt owed to it, such a creditor will generally be deemed to have a secured claim within the bankruptcy proceeding. The primary advantage of that status is that it generally entitles the creditor to receive the value of the property securing its claim. Provided that the lien is given effect within bankruptcy (although the possibility exists that it will not, for reasons discussed below), the creditor will be assured of receiving some distribution in bankruptcy, thus emphasizing the manner in which the lien serves as form of insurance against the risk of nonpayment by the debtor (both outside and inside of the bankruptcy forum). On the other hand, bankruptcy law will generally relegate unsecured creditors (i.e., those without a lien in estate property) to sharing ratably with one another the assets that remain in the common pool after the estate's encumbered assets have been administered. Importantly, not all unsecured claimants are treated alike. Instead, bankruptcy law often confers preferred status upon some unsecured claimants, such as government creditors with tax claims or the claims of the debtor's employees. In these sorts of provisions, one witnesses the public policy rationales at work that certain types of claimants deserve better treatment in bankruptcy than other competing claimants. For example, in the context of government creditors with tax claims, the idea is that bankruptcy law ought to be tailored in such a way that it protects the public fiscus (Morgan, 2000: p. 463), even though doing so may undermine the welfare of general contract creditors.

As the discussion above illustrates, bankruptcy law does not treat all creditors alike, but rather assigns various statuses based upon the nature of the claim. This differential treatment features prominently in the distribution scheme in bankruptcy. The order in which claimants receive payment on account of their claims reflects society's judgment as to the relative merit of claimants. For example, some bankruptcy regimes entitle secured creditors to receive distributions first, whereas other regimes entitle tax claimants to receive distributions prior to certain secured creditors (Morgan, 2000: pp. 474–499). Regardless of the order, creditors will be segregated into various classes based upon the status that bankruptcy law assigns to them. Once the separation has occurred, distributions will be made to the class with the highest priority, followed by distributions to the class with the second-highest priority, and so on and so forth. When insufficient funds remain to pay all members of a class in full, the members will receive a *pro rata* distribution. For those creditors that have been assigned to classes with a lower priority than the class that received a *pro rata* distribution, such creditors will not receive any distribution on account of their claims.

In liquidation proceedings, the debtor's assets will be reduced to money, which in turn will be used to repay creditor claims pursuant to the prescribed distribution scheme. In reorganization proceedings (for legal entities, such as a corporation) and rehabilitation proceedings (for natural persons), the debtor's future income will be used primarily (if not exclusively) to repay creditor claims. In the abstract, creditors as a group should theoretically receive a greater payout when the debtor's income is used as the source of repayment. If the debtor is a legal entity and has a reasonable prospect of being restored to financial health, the income generated by the debtor as a going concern ought to be greater than the amount that would be realized by liquidating the debtor's assets. And, if the debtor is a natural person, the disposable income that he or she generates over time will likely exceed the liquidation value of those assets that the debtor cannot exempt from the bankruptcy process and that are thus available as a source of repayment in a liquidation proceeding. Theory aside, bankruptcy law aims to ensure that creditors involved in a reorganization or rehabilitation proceeding are no worse off, from the repayment perspective, than had the debtor sought relief through a liquidation proceeding. In other words, when future income is the source of repayment, creditors should receive at least as much as they would have received from the proceeds of the debtor's liquidated assets. The latter amount serves as a baseline for confirming that creditors receive equal (if not better) treatment in reorganization and rehabilitation proceedings. Because claim repayment based on future income will involve a deferred stream of future payments, the aggregate amount projected to be paid to creditors must be discounted to its present value (thereby accounting for the time-value of money) when making the comparison to the liquidation baseline.

Given bankruptcy law's preoccupation with vindicating the equality principle, a concern arises when a debtor transfers property or an interest therein (e.g., a consensual lien) to a creditor on the eve of bankruptcy. Specifically, the transfer may render the creditor better off than similarly situated creditors (i.e., those with like legal entitlements), thereby upending what would have been the ordered arrangement for distribution in bankruptcy in the absence of the transfer. Additionally, the debtor may have made the transfer to put the property beyond the reach of its creditors, thereby depleting the estate of that which would have existed in the absence of the transfer. Bankruptcy law responds to these concerns through various avoidance provisions that restore the debtor's estate and the transferee to their prebankruptcy positions by allowing certain prebankruptcy transfers (e.g., preferential transfers and fraudulent transfers) to be recovered for the benefit of all creditors. Such provisions can be viewed as "stabilizing forces" intended to preserve the "scheme of social cooperation" (Rawls, 1971: p. 6) – that is, *ex post* mechanisms for unraveling *ex ante* behavior that would undermine the equality principle.

Implementing the Fresh-Start Principle

When thinking about the manner in which bankruptcy law seeks to implement the fresh-start principle, it is important to keep in mind that the amount of debt that bankruptcy law

forgives is completely unrelated to the distributional treatment that creditors receive on account of the status of their claims (Jackson, 1986: p. 225). Accordingly, rules governing the scope of discharge are distinct from and can coexist peacefully (and not in tension) with distributive rules governing the repayment of creditor claims *within* bankruptcy. On the other hand, implementing other aspects of the fresh-start principle (i.e., provisions unrelated to the discharge of debt) may have the effect of reducing creditor recoveries. For example, any provision that permits the debtor to claim certain prebankruptcy property as exempt (and thus unavailable for distribution) will reduce the amount that creditors will be repaid. Moreover, a discharge of prebankruptcy debt generally precludes a creditor from seeking postbankruptcy repayment from the debtor on account of such debt. One can see from these examples that certain aspects of the fresh-start principle and the equality principle are inversely related such that enlarging the reach of one necessitates narrowing the other's scope (Pardo and Lacey, 2005: p. 415).

Bankruptcy law's core mechanism for implementing the fresh-start principle is the discharge. In its most robust form, the bankruptcy discharge would forgive all prebankruptcy debts irrespective of the identity of the claimants to whom such debts are owed or the circumstances under which such debts were incurred. The law, however, does not afford such generous treatment to debtors and instead curtails the scope of relief to exclude certain debts from being forgiven (e.g., tax debts, fraudulent debts), imposing such restrictions predominantly on natural persons rather than legal entities. Such provisions reflect societal consensus that the fresh start should not be limitless: In other word, society's interest in the repayment of certain types of debts outweighs its interest in forgiving debtors. Discharge exceptions inevitably encroach upon a debtor's fresh start, threatening the ability of the debtor to return to economic productivity. Nonetheless, by excepting certain debts from discharge, bankruptcy law reflects the inherent belief that a debtor will be able to repay its prebankruptcy creditors from postbankruptcy income and/or assets (Boshkoff, 1982: p. 89).

Upon the grant of discharge, bankruptcy law seeks to protect the debtor's fresh start by enjoining efforts by creditors to collect discharged debts as a personal liability of the debtor. Unhampered by the burden of past debts, the debtor can focus his or her attention on reintegrating into the marketplace with the opportunity to make new financial commitments.

Conclusion

Since time immemorial, financial failure has been part and parcel of the debtor–creditor relationship. Inevitably, there will always be those who cannot fully repay their debts. Society must, broadly speaking, determine three things when choosing to address such failure through bankruptcy law: (1) whether to absolve the debtor of past debts; (2) the price that the debtor must pay in exchange for such absolution, and (3) how to allocate the price paid among existing creditors. These determinations necessarily entail intuitions and normative judgments regarding the causes of financial failure, the future ability of debtors to repay their debts, and the worthiness of competing claimants in light of their relative entitlements. Accordingly, when examining the content of bankruptcy law, a rich story unfolds about the manner in which society values remedying financial distress.

Abstract

Roland Barthes was a twentieth-century French literary critic, philosopher, and cultural theorist important in the trajectories of structuralism and poststructuralism. This article begins by examining Barthes' formative years and influences, and highlights his contributions made to structuralism and poststructuralism in France and beyond. The article then discusses the role that Barthes' work has played in the social and behavioral sciences, including how his writings have been appropriated by disciplines such as sociology and anthropology. Barthes' writings on history are also examined in a disciplinary context.

Barthes, Roland (1915–80)

Roland Barthes, born 12 November 1915 in Cherbourg, France, died 26 March 1980 in Paris, was a French literary critic, philosopher, and cultural theorist. He made contributions to the intellectual movements of structuralism and poststructuralism, and to the fields of linguistics, semiotics, and social theory. Elements of Barthes' theory construction have also been employed in social and cultural anthropology, especially his discussion and theorizing of myth. Additionally, Barthes' study of the phenomena of popular media has influenced communication studies, popular culture studies, as well as intellectual niches such as the sociology of fashion, visual sociology, the sociology of art, aesthetics (including aesthetics of photography and music), music criticism, and music sociology.

Formative Years

Roland Barthes was born in Cherbourg, France in 1915. His father was a naval lieutenant killed in a battle 1 year later. By 1924, at the age of nine, Barthes moved with his mother to Paris. It was in Paris that Barthes received the majority of his education. He began by attending the Lycée Montaigne, and then continued his studies at the Lycée Louis-le-Grand, from 1930 to 1934. Ultimately, Barthes studied classical letters, grammar, and philology at the Sorbonne, receiving degrees in 1939 and 1943. He also studied French Literature and Greek tragedy there. It was between 1935 and 1939 that Barthes initially attended the Sorbonne, receiving a license of classical letters in the latter year.

Barthes' subsequent doctoral studies at the Sorbonne were marked by ill health. He suffered from pulmonary tuberculosis, spending time in sanatoriums in the years 1934–35 and 1942–46. The latter years coincided with the French occupation, at which time he had been exempted from military service for health reasons. Despite his medical condition, Barthes managed to read and write, established a theatrical group named the *Groupe de Théâtre Antique*, and also taught.

On 21 October 1939, Barthes was appointed by the Bordeaux education authority to a lycée in Biarritz on a temporary and provisional basis. Formally, Barthes had only been appointed a supply teacher in Biarritz. On return to Paris, Barthes was unsuccessful in securing a similar post, so he became a study and recreation supervisor at two schools, the Lycée Voltaire and the Lycée Carnot. Despite the limited capacity of his formal appointment there, Barthes gained experience as a tutor and professor at the Lycées Voltaire and Carnot.

Barthes' academic career was interrupted by a second attack of tuberculosis in 1941, and a 6-year absence from active work. During this time, he received a license in grammar and philology, published his first article, and, shortly engaged in premedical study with the intention of pursuing a career in psychiatric medicine. It was not until 1948 that he returned to academic work, first at the Institute Français in Bucharest, Romania, and, in 1949–50, at the University of Alexandria in Egypt.

From 1947 to 1950, Barthes contributed a number of articles on literary criticism to the leftist French paper *Combat*. These articles formed the basis of Barthes' first book, which was an 80-page volume entitled *Writing Degree Zero*, and was published in 1953. From 1950 to 1952, Barthes served as Direction Générale des Affaires Culturelles. His teaching career expanded by research positions with the Centre National de la Recherche Scientifique from 1952 to 1959, where he investigated sociology and lexicology. Barthes would go on to hold a directorship of studies at the École Pratique des Hautes Études from 1960 to 1976. He was initially appointed Chef de travaux in the sixth section of the École Pratique des Hautes Études, the Department of Economics and Social Sciences, or Chairman of the Section of the Social and Economic Sciences, and then 2 years later, Directeur d'études in the Sociology of Signs, Symbols, and Representations. He remained in the latter post for 14 years, until his election to the Collège de France. On 14 March 1976, following a recommendation made by French philosopher Michel Foucault (1926–84), the committee of professors at the Collège de France elected Barthes to a Chair of *Sémiologie Littéraire* (Literary Semiology), which he accepted and held until his death in 1980.

In 1952, when Barthes had joined the Centre National de la Recherche Scientifique, he first engaged in research in lexicology, and then followed in sociology. The earliest product of these studies was a series of amusing examinations and demystifications of contemporary French popular culture myths, the languages of mass culture such as wrestling, soap powders and detergents, toys, Einstein's brain, popular attitudes toward science, wine and milk, and steak and chips.

These analyses were initially contributed each month, from 1954 to 1956, to *Les Lettres Nouvelles*, and were finally gathered and published in a volume entitled *Mythologies* in 1957. This early work on popular culture by Barthes was concerned with the processes of signification, the mechanisms by which meanings were produced and distributed, or how they emerged and were put into circulation. His guiding principle throughout remained to interrogate the falsely obvious and to make explicit what too often remained implicit in the texts and practices of popular culture. One of his purposes was political, with his target being what he considered the bourgeois norm of modern French society.

Mythologies also served as Barthes' most significant attempt to bring the methodology of semiology to bear on popular culture. The volume concluded with the important theoretical essay, 'Myth Today,' and in the essay, Barthes outlined a semiological model for reading popular culture as though it were a text. *Mythologies* was widely read, and intellectual life in France was entering a new period of inquiry when the volume of essays first appeared in 1957. It soon formed part of the literature of the nation's new intellectual movement that of structuralism.

Barthes was one of the early proponents of structuralism in France in the 1950s, and would go on to develop post-structuralism in the 1960s. The primary influence in Barthes' intellectual development was Swiss linguist Ferdinand de Saussure (1857–1913), namely his *Course in General Linguistics*, which had been posthumously published in 1916. In general, Barthes was aware, and, to a certain degree, a disciple, of the structuralism of French anthropologist Claude Lévi-Strauss (1908–2009), including his structural study of myth. To a lesser acknowledged extent, nineteenth-century French sociologist Émile Durkheim (1858–1917), namely his social theories of collective representations and collective conscience, also were influential in the development of Barthes' cultural theory and criticism. Barthes was aware of Durkheim's writings well before the work of Saussure. Barthes was originally labeled one of the four major figures of structuralism in France, along with Lévi-Strauss, psychoanalyst Jacques Lacan (1901–81), and Foucault, with all but Lévi-Strauss ultimately renouncing structuralism and moving into phases of poststructuralism in the 1960s. The other two thinkers that influenced Barthes' structuralism, especially its semiological dimension, were Russian–American linguist Roman Jakobson (1896–1982) and Danish linguist Louis Hjelmslev (1899–1965).

Semiology and Myth

Barthes' semiology took up Saussure's claim that his linguistic theories could be used to study the wider life of signs in society. Accordingly, Barthes applied those theories to the postwar culture of goods, objects, and message in France to understand these as signs within a system of meaning generated in both their collective, structurally interrelated and individual, internally structured relationships, including their second-order cultural connotation, which Barthes referred to as myth. Although the term semiology had been coined at the beginning of the century by Saussure in his *Course in General Linguistics*, and despite it being defined by him systematically as the science, which studies the existence of the signs at the heart of social life, Barthes believed that a science had still not been conventionally introduced to the academic world.

In the mid-1960s, Barthes, therefore, found himself at the forefront of a major theoretical debate, which would place him against the advocates of orthodox linguistics. Barthes started down such a path in *Writing Degree Zero*, where he had reflected on the historical condition of literary language, and on the fact that all language is constricted by its previously ascribed meaning, and that it exists in a specific culture and, therefore, is always full of implicit assumptions about a given social reality. In addition to opposing the orthodoxies of linguistics at the university level, Barthes also complained of academic literary criticism, and did so in *Writing Degree Zero*. One of his complaints was that the academic criticism was psychologically naïve and deterministic. Moreover, Barthes felt it operated with a model of the human personality that was made obsolete by the discoveries of psychoanalysis.

In 1963, in the publishing of his *Elements of Semiology*, Barthes went on to argue how language and speech in their reciprocal relation complement Durkheim's concept of a collective conscience. Barthes, as a structuralist, wanted to locate the importance of the unspoken, unconscious language in the act of writing. He examined the desire and emotion that formed part of written texts, and did so in relation to politics and social life. In *Mythologies*, he focused on the hidden, unconscious messages by the mass media that promote capitalist ideologies. In his unmasking of all ideologies to destroy their effectiveness, Barthes had found that both capitalist and revolutionary languages perpetuate their own myths.

Barthes' method of reading myths like a text derived from his experience as a mythographer. The method also derived from linguistics, or, more precisely, semiotics, the latter understood as the study of sign systems and signification. Barthes made a distinction between denotation of a sign and its connotation, where denotation was the literal meaning, and the connotation was its mythical meaning. Connotation was classified as a symbolism, since connotations were additional meanings present along with the literal meaning of the sign that was in question. Barthes found in 'Myth Today' that myth was constituted by the loss of the historical quality of things, and in it, things themselves lost the memory of their own fabrication.

In *Elements of Semiology*, Barthes referred to the term denotation as primary signification and the term connotation as secondary signification, where the first system of denotation became the plane of expression or signifier of the second system of connotation. The signifiers of connotation were comprised of signs, signifiers, and signifieds united of the denoted system. Barthes argued that it was at the level of secondary signification or connotation that myth was produced for consumption. Myth in such an intellectual and social context referred to ideology as though it were understood as a body of ideas and practices, whereby actively promoting the values and interests of dominant groups of society, defended customary structures of power.

In cultural theory, Barthes' work provided a definition of ideology. Barthes argued that ideology, or myth, operated mainly at the level of connotation, the secondary, often unconscious meanings that texts and practices carried, or could be made to carry. At the time, it was the very concept of

connotation, taken from the work of Hjelmslev, which enabled Barthes to move between the realms of the scientific and the political. In 'Myth Today,' Barthes located ideology on the level of connotation, in what not was said explicitly but in what was implied and thus carried an even greater force. Where he came to propound a theory of semiotics in order to justify his practice of it, Barthes relied heavily on the work Hjelmslev, most notably his brief remarks that distinguished semiotic systems, which denote from those which also connote. Barthes himself was a scholar of connotations, not of denotations. He believed semiotics has to take its lead from linguistics.

Also in cultural theory, it has been argued that Barthes was one of the leading practitioners of semiotics as a political reading of society. Such an argument in this field treats Barthes' *Mythologies* as a series of cutting essays in the interpretation of a number of French cultural phenomena from a near-Marxian perspective. For the Barthes of *Mythologies*, the practice of semiosis was considered hygiene, and it brought to light the abusive way in which signs could be used by one powerful social group at the expense of others. Barthes employed the term myth there in a deliberately tendentious way to refer to such systematic abuse of the process of signification. According to Barthes, there were no limits as to which objects may be so abused.

In the volume *The Rustle of Language*, a collection of 45 essays written between 1967 and 1980, Barthes paid homage to Jakobson and the young Bulgarian–French philosopher Julia Kristeva (1941–), namely their contributions to semiotics. Nonetheless, it was Barthes' *Elements of Semiology* that represented his formal and systematic study in the mechanics of semiotics. The latter publication gave Barthes a solid reputation as a semiotician in France and beyond. This and many other works by Barthes were measured reflections on language sign systems, texts, and the very nature of what they were able to tell us about the human condition. In particular, *Elements of Semiology* was a prime example of scholarship in continental philosophy of language, a study that was partially indebted to the French tradition in the human sciences on one hand, and, on the other hand, an exercise in literary studies. Barthes' work, including *Elements of Semiology*, gained him a reputation in contemporary theory in the humanities and social sciences for searching for common forms taken by sign systems, myths or connotations across all the domains studied, and looking for oppositions, or binary relationships, between domains such as nature and culture, as well as essence and history. Barthes made it clear that the structural study of myth could only supply one half of the truth, and that the other half had to be supplied by empirical means, or by sociology, which involved the practice of quantification.

It was 'Myth Today,' along with *Elements of Semiology* and his work *The Fashion System*, which made up Barthes' second semiological period, and which immediately followed *Writing Degree Zero*. The publication of *Mythologies*, including 'Myth Today,' marked a period of Barthes' career in which he was beginning to elaborate his theoretical framework, one that became increasingly preoccupied by political issues. His Marxism started to push him toward the Communist Party in France, in a collegial manner, but his well-known fainthearted and unsure demeanor ensured that he remained at a distance from their affairs. He discussed his doubts with colleagues in Paris in the 1950s, explaining his worries about that party, and how he was tired of seeing intellectuals paralyzed, unable to decide where they stood in relation to communism. Of most significance, Barthes was depressed by the diminished importance left-wing intellectuals held in France. He was confronted with many contradictory opinions from people he respected, and such confrontations gave him the feeling that his interests in French intellectual and social life had shifted, going awry in the process.

Structuralism

Barthes accepted the label of structuralist at least as a historical label for his work produced in the late 1950s and the majority of the 1960s. Although it is difficult to mark with accuracy the beginnings and end of Barthes' structuralist phase, intellectual histories commonly associate the rise of structuralism as a modern intellectual movement in France with the publication of Lévi-Strauss' *Tristes Tropiques* in 1955. Barthes used the label more cautiously than the majority of others, and associated it exclusively with Saussure's linguistics, which it appears he had not studied until just before composing the earliest essays of *Mythologies*, not any earlier than 1952. The titles of Barthes' two most explicitly structuralist studies suggest brevity in duration and are 'The Structuralist Activity' (1963) and 'An Introduction to the Structural Analysis of Narrative' (1966). The latter was originally published in the journal *Communications*, of which Barthes was a founding editor. *Elements of Semiology* has also been referred to by Barthes scholars as a structuralist study, mostly because of its Saussurean basis. In Barthes' 'Introduction to the Structural Analysis of Narratives,' he began by reminding the reader that narrative was as old as human civilization, and that, therefore, there were simply countless narratives, which could be analyzed. He found that the structural analysis of narratives modeled itself on linguistics. It was linguistics, Barthes found, that stopped at the level of the sentence. Accordingly, he found that it took the sentence at its highest term and proceeded to study all the rules of combination and opposition, which allowed for sentences to be constructed.

Barthes wrote pieces for the literary magazine *Esprit*, in addition to *Les Lettres Nouvelles* and *Combat*. In 1960, a new review called *Tel Quel* was launched, with Barthes collaborating and forming part of its group of intellectuals in France in the 1960s, which included Kristeva, Foucault, and philosopher Jacques Derrida (1930–2004). *Tel Quel* was essentially an avant-garde literary magazine, and Barthes published many essays there. According to him, *Tel Quel* represented the dialectical articulation of a revolutionary, Marxian political stance and an avant-garde cultural activity. Nonetheless, Barthes spent the majority of protests during May 1968 at *Tel Quel* meetings, far removed from the demonstrations and the lecture theaters, as he believed that structures did not 'take to the streets.' By the end of May 1968, the intellectual movement had all but extinguished itself in the pages of *Tel Quel*, the very journal it and its luminaries such as Barthes had established for reasons of promotion.

Outside of France, the reaction against structuralism that May 1968 symbolized went largely unnoticed and many across the rest of the world at this time were only beginning to hear

about structuralism and about one of its proponents named Roland Barthes. Until 1967, *On Racine* was the only one of Barthes' books that had been translated into English. However, later that year English translations of *Writing Degree Zero* and *Elements of Semiology* appeared, and Barthes' reputation as a structuralist began to spread widely. It is in such a fashion that Barthes has been identified as one of the French theorists' who most changed the intellectual landscape of the American academy across the arts, humanities, and social and behavioral sciences.

Barthes' identification as a structuralist was helped by his visits to Japan and the United States in 1966. It was his trip to the United States in October, at Johns Hopkins University in Baltimore, Maryland, that he delivered a paper at an International Symposium on 'The Languages of Criticism and the Sciences of Man,' the events of which were later published as *The Structuralist Controversy* (1970). Nevertheless, by 1968, primarily in his seminar at the École Pratique, Barthes was already engaged in the analysis of a novella by the nineteenth-century French novelist Honoré de Balzac (1799–1850), *Sarrasine*, the result of which appeared in print by Barthes as *S/Z* and marked what, for lack of a better term, has been referred to as his poststructuralist phase. In *S/Z*, Barthes developed a structural analysis of narrative in the context of the fiction of Balzac's *Sarrasine*, with such analysis widely considered a high point of his poststructuralist phase.

Poststructuralism

Barthes himself described his poststructuralist phase as a period marked by his concern with textuality. The textual, in Barthes' sense, is not to be identified with the state of a physical text, as he believed the texts that writers work with are held 'only in language, not in the hand.' Barthes' first three books of his poststructuralist phase each supplied an example of this conviction. In *S/Z*, published in 1970, the text was not Balzac's *Sarrasine*, but Barthes' reading of that story as a language. In *Empire of Signs*, which was published the same year, the text was Japan, a country, which Barthes managed to read. The following year, Barthes published *Sade, Fourier, Loyola*, which took as its basis three texts, or three languages. In contrast to his earlier structural analyses, these three textual studies of Barthes emphasized the process of the text itself, not a closed structure.

In May 1966, Barthes went to Tokyo at the invitation of the director of the Franco-Japanese Institute. He gave a seminar on the structural analysis of narrative. Between 1966 and 1967 he went there three times, bringing back with him from the few weeks he spent there the material for the book on Japan he would eventually write entitled *Empire of Signs*. After the last of Barthes' travels to Japan, he published *Empire of Signs* in 1970. In *Empire of Signs*, Barthes brought to the critical forefront the problem of analyzing history and culture, or the cultural history of Japan, from an ostensibly objective point of view. Barthes' semiotic method seemed to transform history into historiography, or the writing of history. It was at such juncture that Barthes made the reader aware of the way in which the authority of history in the West is grounded in the logic of what the scholars of ancient Greek referred to as the metaphysical *logos*. Barthes found that the *logos* functioned as the mystical power of the word of God, to that which incarnated meaning and reason in the word. In such a sense, Barthes found that history itself functioned as the word, leading him to argue that the reason of history was the reason of the word. Such a presupposition of Barthes enabled him to generate a vision of culture that was recorded as history, with history also recorded as culture, or the writing of cultural history through which the meaning of culture was codified in a system and represented as the truth. Accordingly, *Empire of Signs* represented a prime example of Barthes' teasing out the practice of writing history and representing culture, or writing cultural history, within the logic of poststructuralism. On such grounds, *Empire of Signs* reflected Barthes' attempt to transgress the cultural boundaries of historical writing and semiology.

Whereas the early work of Barthes intended to unlock the secrets of representational forms such as mythology, his later work complicated the simplicity of that notion, and even questioned its relevance with respect to the cultural production of meaning. Signs, codes, structures, and systems were all still important in his later work, such as *Empire of Signs*, but mainly as conventions to be played with and enjoyed. Gone were the inventories and labels that enabled Barthes, as semiologist, to produce a metalanguage of scholarly inquiry. In *S/Z*, *The Pleasure of the Text*, and *A Lover's Discourse*, Barthes was not so much interested in what was represented and how, as he was in generating new ways of reading for their own sake.

Barthes' essay 'The Death of the Author' (1968) represented a prime intellectual influence in the field of literary criticism and theory. His 'From Work to Text' was an extremely important piece in the area of continental aesthetics, and his book *Camera Lucida: Reflections on Photography* (1980) was important to aesthetics as a scholarly field. His volume of collected essays translated and published in English as *Image-Music-Text* (1977) included 'The Death of the Author' and 'From Work to Text,' and represented an important compilation of essays on aesthetics in the tradition of poststructuralism. Works of his such as 'The Plates of the *Encyclopedia*' (1964) from his *New Critical Essays*, translated and published in English in 1980, are representative of the core of continental aesthetics in the poststructuralist tradition. Barthes also wrote on fashion, with his *The Fashion System* published in 1967, representing an analysis of fashion and its semiotics, which marked an early contribution to visual sociology and the sociology of fashion.

Barthes turned extensively to literary studies in the 1970s with the publication of *S/Z: An Essay* in 1970, and *The Pleasure of the Text* in 1975. His *A Lover's Discourse: Fragments*, published in 1978, sold 60 000 copies in France. He employed the methodologies of structuralism and poststructuralism to understand the phenomena of love. His literary study *On Racine* has been published in France in 1963. He would go on to practice the art of writing autobiography with the publication of his *Roland Barthes by Roland Barthes* in 1975. He published more literary criticism and theory in 1980, marked by *Sade, Fourier, Loyola*. A notable theory from this work surrounds the way he studies the different modes of reception and evaluation of a text, and proposes a distinction between a 'writerly' (*scriptable*) text, where the reader can rewrite, or desires to write, and a 'readerly' (*lisible*) text, which can only be read. With the publication of *The Pleasure of the Text*, Barthes examined the relationship between pleasure, ecstasy, the untranslatable French term *jouissance*, and desire. The day

after his mother's death in October 1977, he began a diary of mourning that would come to be published as *Mourning Diary*. Recently, Barthes' lectures at the Collège de France from the late 1970s have been translated into English for the first time, including *The Neutral* (1977–78) and *The Preparation of the Novel* (1978–79 and 1979–80), as well as his first course at the Collège after being elected to his Chair there, *How to Live Together* (1976–77). In 1974, Barthes went to China with Kristeva and others, agreeing to write an article about his experience for *Le Monde* on his return to France. Recently, his *Travels to China* have been published in English. His posthumously published Collège de France lectures and courses reveal how he went about incorporating influences from the orient in his literary criticism and theory.

Barthes' Influence in the Social and Behavioral Sciences

In the social and behavioral sciences, Barthes' influence primarily rests on social theory, sociological theory, the sociology of consumer culture, the sociology of culture/cultural sociology, and theory in social and cultural anthropology. Much of the early work done in the field of contemporary cultural studies, including its theoretical framework, rests on Barthes' writings. This is especially the case of his essays that comprise *Mythologies*, such as 'The World of Wrestling.' The work forms an integral part of analysis in cultural theory and popular culture studies, and bridges the humanities with the social and behavioral sciences. Some of his work has been influential in the development of the sociology of literature, and in general, social and cultural criticism, including the sociology of everyday life and the sociology of leisure. Some of his essays have formed a basis for the sociology of media as well.

For Barthes, the human sciences were a reformation of traditional humanism along lines of several modern intellectual movements, especially those in linguistics, which now were employed as a tool for analyzing any social practice as a language. As a result, the imprecise concept of the human could be demystified and studied scientifically. In his essay 'From Science to Literature' (1967), Barthes begins with a discussion of the function the social and human sciences serve in the French university system, and what the term 'science' actually signifies. Barthes held the conviction that structuralism would never be anything more than another science, and expressed so in 'From Science to Literature.' Barthes saw the opposition between science and literature of being of particular importance to structuralism. Barthes characterizes structuralism as paying special attention to classifications, orders, and arrangements. Further, he finds it is in such a fashion that it comprises forms of discourse. Barthes was interested in the general mythology that each literary work participated in, and that which affected the contents of structuralism. On his account, the contents included the inner logic that governs each literary work as myth.

Barthes' work *Michelet* was published in France in 1954, and was a critical analysis of the French historian Jules Michelet (1798–1874). The work inspired a revival of interest in the eminent nineteenth-century historian. Another of Barthes' essays, 'The Discourse of History' (1967), examined semiotics and continental philosophy of language among history, as traditionally understood in the framework of the human sciences. In historical writing, including the discourse of history, Barthes essentially scanned a historical text for traces of the writing subject. He at first found 'shifters,' a term borrowed from Jakobson. These were divided among testimonial shifters, organizing shifters, and shifters that marked interventions of the writer or that which appealed to the listener, whereas testimonial shifters marked the presence of the historian as someone who gathered and weighed up evidence from other sources, and organizing shifters represented where narration diverges from chronological sequence and reorganized itself according to the needs of the discourse, ultimately establishing its own structure of a temporal nature.

'The Discourse of History' attacked that discourse's pretension to deliver 'the facts' guaranteed by 'the real.' Barthes' essay argued that the discourse of history performed a sleight of hand whereby a discursive operator, the referent, was projected into a realm supposedly beyond signification, from which position it could be thought to precede and determine the discourse, which posited it in its very capacity as referent. Barthes claimed that such a paradox governed the entirety of the question of the distinctiveness of historical discourse, as he found the fact could only have a linguistic existence, as a term in a discourse, and yet it was exactly as if this existence were merely the 'copy,' purely and simply, of another existence situated in the extra-structural domain of what was the 'real.' This type of discourse was doubtless the only type in which the referent was targeted for something as external to the discourse without it ever being possible to attain it outside its confines. Barthes went on to propose an eminently structuralist account of such an operation, where he argued that the discourse of history is guilty of reducing the three-term structure of signification (signifier-signified-referent) to a two-term structure (signifier-referent), or rather, smuggling into such an ostensibly two-term structure an illicit signified, a 'real in itself,' which furtively transformed into an awkward signified. Historical discourse did not follow what was 'the real' for Barthes, as he felt it could do no more than signify 'the real,' in the capacity of constantly repeating that it happened, without such an assertion amounting to anything more than the signified reverse side of the entirety of the process of historical narration itself.

Barthes' interests in popular media and events were due in part to what he saw as an abuse in such phenomena of ideology. He conflated elements of what had been perceived as 'high' or 'low' culture. In November 1964, in the journal *Communications*, Barthes published his essay 'Rhétorique de l'image' ('Rhetoric of the Image'), which was comprised of an analysis of one poster advertising Panzani pasta. This and other writings examined the semiology and sociology of advertising. Barthes' *The Fashion System* was part sociology of fashion. His 'History and Sociology of Clothing' was published in French in the *Annales* in 1957, and his 'For a Sociology of Clothing' was published in French there in 1960. *The Fashion System* included these essays, and the entirety of the manuscript was labored over by Barthes from 1957 to 1963. He decided not to publish it until 3 years later, at which time it merely represented a document in the history of semiology.

Barthes also wrote music criticism, and other of his writings involved the aesthetics of music, and aesthetics, in general, and to a lesser degree, music sociology. The full extent of Barthes'

music criticism, aesthetics of music, and music sociology are collected in the latter part of a volume of his essays entitled *The Representation of Forms*, which was published in English in 1991. Barthes did much to shift the textual study of popular music away from the traditional concerns of musicologists and onto semiotic questions of representation and meaning, as well as emphasizing the pleasures of the text, or musical work. Barthes' essay 'The Grain of the Voice' is generally regarded in cultural theory as the work that laid the ground for a textual study of popular music. Barthes complained in this essay that music critics were obsessed with adjectives and that such intimidation of detail actually served to prevent an adequate understanding of the text. In order to grasp the meaning of a musical experience, Barthes argued that one ought to dispense with trying to capture the minutiae but instead respond directly to its surface, the so called 'grain of the voice' that was expressed in the materiality of its body.

Abstract

This article describes a class of graphical models known as directed acyclic graphical (DAG) models. These models have numerous uses including data analysis, modeling of causal relationships, and representing and reasoning about uncertainty in expert systems and decision analysis. In this article, we define the model class and describe its basic properties. In addition, we discuss how DAG models are used in expert systems and decision analysis, and describe methods for inferring the structure and distributions of DAG models from data.

Introduction

A graphical model represents the probabilistic relationships among a set of variables. Nodes in the graph correspond to variables, and the absence of edges corresponds to conditional independence. Graphical models are becoming more popular in statistics and in its applications in many different fields for several reasons. For example, they provide a language to facilitate communication between a domain expert and a statistician, provide flexible and modular definitions of families of probability distributions, and are amenable to scaleable computational techniques (e.g., Pearl, 1988; Lauritzen, 1996; Whittaker, 1990).

The subject of this article is directed acyclic graphical (DAG) models. These models have numerous uses including data analysis (e.g., Whittaker, 1990; Spiegelhalter and Thomas, 1998), modeling of causal relationships (e.g., Pearl, 2000; Spirtes et al., 2001), and representing and reasoning about uncertainty in expert systems (e.g., Cowell et al., 1999). Specific applications of graphical models include diagnosis and troubleshooting, medical monitoring, genetic counseling, information retrieval, natural language processing, weather forecasting, manufacturing, digital communication, and machine vision.

In the section 'Definition and Basic Properties,' we define the DAG model and describe its basic properties. In the section 'DAG Models for Expert Systems and Decision Analysis,' we describe the use of DAG models in expert systems and decision analysis. In the section 'Learning DAG Models from Data,' we describe methods for constructing the structure and distributions of DAG models from data. In the section 'Pointers to the Literature' we conclude with additional pointers to the literature.

Definition and Basic Properties

Let us begin with some notation. We denote a variable by a capitalized token (e.g., X, X_i, Θ, *Age*), and the state or value of a corresponding variable by that same token in lower case (e.g., x, x_i, θ, *age*). We denote a set of variables by a bold-face capitalized token (e.g., $\mathbf{X}$, $\mathbf{X}_i$, $\mathbf{Pa}_i$). We use a corresponding bold-face lower-case token (e.g., $\mathbf{x}$, $\mathbf{x}_i$, $\mathbf{pa}_i$) to denote an assignment of state or value to each variable in a given set. We use $p(x|y)$ to denote the probability or probability density that $X = x$ given $Y = y$. We also use $p(x|y)$ to denote the probability distribution for X given Y. Whether $p(x|y)$ refers to a probability, probability density, or a probability distribution will be clear from context. Finally, we use $\mathbf{X} \perp \mathbf{Y} | \mathbf{Z}$ to mean that $\mathbf{X}$ and $\mathbf{Y}$ are conditionally independent given $\mathbf{Z}$.

A DAG model for a set of variables or *domain* $\mathbf{X} = \{X_1, \ldots, X_n\}$ consists of (1) a network structure $\mathbf{s}$ that encodes a set of conditional independence assertions about variables in $\mathbf{X}$, and (2) a set $\mathbf{p}$ of local probability distributions associated with each variable. Together, these components define the joint probability distribution for $\mathbf{X}$. The network structure $\mathbf{s}$ is a directed acyclic graph, that is, each edge is directed and there are no paths along these directed edges that lead from a variable to itself. The nodes in $\mathbf{s}$ are in one-to-one correspondence with the variables $\mathbf{X}$. We use X_i to denote both the variable and its corresponding node, and $\mathbf{Pa}_i$ to denote the parents of node X_i in $\mathbf{s}$ as well as the variables corresponding to those parents. The *lack* of possible directed edges in $\mathbf{s}$ encode conditional independencies. In particular, given structure $\mathbf{s}$, the joint probability distribution for X is given by

$$p(\mathbf{x}) = \prod_{i=1}^{n} p(x_i|\mathbf{pa}_i) \qquad [1]$$

The *local probability distributions* P are the distributions corresponding to the terms in the product of eqn [1]. Consequently, the pair $(\mathbf{s}, \mathbf{p})$ encodes the joint distribution $p(\mathbf{x})$.

As an example, consider **Figure 1**, which illustrates the structure of a DAG model for troubleshooting a printing problem on the Microsoft Windows 95 operating system. This model structure was constructed from expert knowledge using judgments of cause and effect. Note that, in general, the probability distributions in a DAG model may be subjective or objective.

In the remainder of this section, we discuss several basic issues concerning DAG models. Equation [1] implies that, for all X, the nondescendants of X are independent of X given the parents of X. Many additional independencies are entailed by this basis of independencies. In **Figure 1**, for example, we have that *Print Output OK* and *Application Output OK* are

Figure 1 A DAG model for troubleshooting a printing problem.

conditionally independent given *Print Data OK*. Pearl (1988) describes a condition, called *d-separation*, that allows one to read off any independency from a DAG model in a computationally efficient manner.

Another commonly used graphical model is the undirected graphical (UG) model, also known as a Markov Random Field or Markov Network (e.g., Whittaker, 1990; Lauritzen, 1996). The independencies that can be encoded by DAG and UG models overlap, but there are independencies that can be encoded by UGs and not DAGs, and vice versa. For example, consider the UG model in **Figure 2(a)** for the domain (X, Y, Z, W). This graph encodes the independencies $X \perp Z | (Y, W)$ and $Y \perp W | (X, Z)$. There is no DAG model for these four variables that can encode both of these independencies. In contrast, consider the DAG model in **Figure 2(b)** for the domain (X, Y, Z). This graph encodes the marginal independence of X and Z and the possible dependence of X and Z given Y. No UG model for these variables can encode this set of relationships.

Figure 2 Undirected (a) and directed (b) graphical-model structures.

The relationships encoded by the 'v structure' or 'collider' in **Figure 2(b)** has an intuitive explanation. For example, consider the subgraph in **Figure 1** for the variables *Correct Local Port*, *Local Cable Connected*, and *Local Path OK*, which has this structure. Before one observes the value of *Local Port OK*, the remaining two variables are marginally independent. When we observe that *Local Port OK* is false, however, the remaining two variables become dependent. If – say – *Correct Local Port* subsequently is observed to be false, then *Local Cable Connected* is more likely to be true, because the faulty local path has been explained by the first observation. In general, this pattern of relationships is sometimes referred to as the 'explaining away' phenomenon (Pearl, 1988).

Another interesting point about DAG models is that two or more DAG models can be equivalent in the sense that they represent the same independencies. Given the domain (X, Y, Z), for example, the DAG models $X \rightarrow Y \rightarrow Z$, $X \leftarrow Y \rightarrow Z$, and $X \leftarrow Y \leftarrow Z$ encode the same independency: $X \perp Z | Y$. Chickering (1995) describes a simple and computationally

efficient algorithm for determining whether two DAG models are equivalent. First, he defines a directed edge from X to Y to be *covered* if the parents of X and Y are the same with the exception that X is also a parent of Y. He then proves that two DAG models are equivalent if and only if there exists a sequence of reversals of covered directed edges that transforms one model to the other.

Finally, we note that the definition of DAG model does not restrict the form of the local distributions $p(x_i|\mathbf{pa}_i)$. Later, we describe several commonly used models for local distributions. Here, we mention that, when a variable and its parents are continuous, a commonly used local distribution is the linear regression with Gaussian error. When all variables in a domain are continuous and the error terms are mutually independent, the resulting DAG model is equivalent to a structural equation model with independent errors (e.g., Pearl, 2000).

DAG Models for Expert Systems and Decision Analysis

The modern use of DAG models began with researchers in Management Science and AI communities (e.g., Howard and Matheson, 1981) who used them to encode prior or 'expert' knowledge for decision making and expert-system inference. These communities refer to this class of model as Knowledge Maps and Bayesian Networks, respectively. In this section, we examine this use of DAG Models.

First, let us consider how a person – who we will call the decision maker – constructs a DAG model for a given domain $\mathbf{X}$ from their knowledge. One method for construction starts with a total ordering on the variables provided by the decision maker. For simplicity, let us relabel the variables $\mathbf{X} = (X_1, \ldots, X_n)$ so that X_i is the ith variable in this ordering. From the chain rule of probability, we have

$$p(\mathrm{x}) = \prod_{i=1}^{n} p(x_i|x_1, \ldots, x_{i-1}) \qquad [2]$$

For every X_i there will be some subset $\Pi_i \subseteq \{X_1, \ldots, X_{i-1}\}$ such that X_i and $\{X_1, \ldots, X_{i-1}\}\backslash\Pi_i$ are conditionally independent given Π_i, that is, for any $\mathbf{x}$

$$p(x_i|x_1, \ldots, x_{i-1}) = p(x_i|\pi_i) \qquad [3]$$

Combining eqns [2] and [3], we obtain

$$p(\mathbf{x}) = \prod_{i=1}^{n} p(x_i|\pi_i) \qquad [4]$$

Comparing eqns [1] and [4], we see that the variables sets $(\Pi_1, \ldots, \Pi_n)$ correspond to the DAG-model parents $(\mathbf{Pa}_1, \ldots, \mathbf{Pa}_n)$, which in turn fully specify the directed edges in the network structure $\mathbf{s}$. Consequently, to determine the structure of a DAG model, a decision maker (1) orders the variables somehow and (2) determines the variables sets that satisfy eqn [3] for $i = 2, \ldots, n$. Finally, the decision maker assesses the local distributions $p(x_i|\mathbf{pa}_i)$.

The approach for constructing model structure just described has an important drawback. If one chooses the variable order carelessly, then the resulting network structure may fail to reveal many conditional independencies among the variables. Fortunately, there is another often-used technique for constructing DAG models that does not require an ordering. The approach is based on two observations: (1) people can often readily assert causal relationships among variables and (2) absent causal relationships typically correspond to conditional independencies. Thus, to construct a DAG model for a given set of variables, one simply draws arcs from cause variables to their immediate effects. In almost all cases, doing so results in a network structure that satisfies the definition eqn [1]. The DAG model in **Figure 1** was constructed in this manner.

Once a DAG model is constructed (whether from prior knowledge, data, or both), we can use it to answer probabilistic queries. In the context of decision analysis, the answers to these queries can be used for decision making. In the context of expert systems, these answers convey 'expert advice.' For example, given the DAG model in **Figure 1**, we may be interested in the probability that *Printer On* and *Online* is true, given *Print Output OK* is false. We can obtain this probability by applying the rules of probability to the joint distribution defined by the DAG model. Many researchers refer to this process as *probabilistic inference*.

Direct computation via the joint distribution is expensive. Investigators, however, have developed probabilistic-inference algorithms that use the conditional independencies in the DAG model to speed up inference, sometimes dramatically. Many of these algorithms are limited to DAG models in which all variables are discrete. For example, Howard and Matheson (1981) and Shachter (1988) developed an algorithm that reverses arcs in the network structure until the answer to the given probabilistic query can be read directly from the graph. In this algorithm, each arc reversal corresponds to an application of Bayes's theorem.

Pearl (1988) developed a message-passing scheme that updates the probability distributions for each node in a DAG model in response to observations of one or more variables. Lauritzen and Spiegelhalter (1988) created an algorithm that first transforms the DAG model into a tree where each node in the tree corresponds to a subset of variables in $\mathbf{X}$. The algorithm then exploits several mathematical properties of this tree to perform probabilistic inference. Lauritzen (1992) extended this algorithm to include DAG models that encode multivariate-Gaussian or Gaussian-mixture distributions.

When the edges of a DAG model structure form a tree, these methods for exact probabilistic inference scale linearly in the number of domain variables. In general, however, these algorithms are NP-hard (Cooper, 1990). The source of the complexity lies in undirected cycles in the DAG model – cycles in the structure where we ignore the directionality of the edges. When a DAG model contains many undirected cycles, inference is intractable. For many applications, however, structures are simple enough (or can be simplified sufficiently without sacrificing much accuracy) so that inference is efficient. For those applications where generic inference methods are impractical, researchers are developing techniques that are custom tailored to particular network topologies or to particular inference queries. In addition, approximate algorithms involving Monte Carlo techniques (e.g., Spiegelhalter and Thomas, 1998) and variational methods (e.g., Jordan, 1998) are proving useful in many applications.

Learning DAG Models from Data

There are a variety of methods for constructing DAG models from data or a combination of data and prior knowledge. We concentrate here on the Bayesian approach, but briefly consider other approaches.

First, suppose the structure $\mathbf{s}$ of the DAG model is known and we are interested in inferring the local distributions from our prior knowledge and a set of data $\mathbf{d} = (\mathrm{x}^1, \ldots, \mathrm{x}^N)$ considered to be a sample from an infinitely exchangeable sequence. For simplicity, we assume that each local distribution is parametric so that the data form a random sample from

$$p(\mathbf{x}|\boldsymbol{\theta}_s, \mathrm{s}) = \prod_{i=1}^{n} p(x_i|\mathbf{pa}_i, \boldsymbol{\theta}_i, \mathbf{s}) \qquad [5]$$

where $\boldsymbol{\theta}_s = (\boldsymbol{\theta}_1, \ldots, \boldsymbol{\theta}_n)$ are the parameters of the local distributions.

If the parameters in $\boldsymbol{\theta}_s$ are mutually independent and there are no missing data, then the parameters in $\boldsymbol{\theta}_s$ are independent *a posteriori* and we can infer each local distribution separately. Because a local distribution can be thought of as a probabilistic classification or regression model, learning the local distributions of a DAG model under the assumptions above is a familiar task. Examples of classification/regression models that have been used in conjunction with DAG models include probabilistic decision trees, generalized linear models, neural networks, and probabilistic support-vector machines.

One class of local distributions used frequently are distributions from the exponential family. For example, when X_i and its parents are discrete, $p(x_i|\mathbf{pa}_i, \boldsymbol{\theta}_i, \mathbf{s})$ can be a set of mutually independent multinomial distributions, one for each instance of the parents of X_i. When X_i is continuous, $p(x_i|\mathbf{pa}_i, \boldsymbol{\theta}_i, \mathbf{s})$ can be a set of linear regressions with mutually independent error terms, one for each instance of the discrete parents of X_i. In these cases, the posterior uncertainty can be determined and integrated over in closed form (e.g., Heckerman and Geiger, 1995).

When the parameters in $\boldsymbol{\theta}_s$ are not mutually independent, when there are missing data (and/or latent variables), when local distributions from outside the exponential family are used, or when complex expectations over posterior uncertainty are required, closed-form expressions are unavailable and Markov Chain Monte Carlo methods are often employed. The BUGS system (Spiegelhalter and Thomas, 1998) is a popular software tool designed for these situations. If maximum-likelihood or maximum *a posteriori* (MAP) approximations are sufficient, then optimization-based algorithms such as Expectation–Maximization and gradient descent typically are used.

Now, let us suppose that we are also uncertain about the structure of the DAG model. Again concentrating on the Bayesian approach, we model this uncertainty with a probability distribution $p(\mathbf{s})$ over the possible structures (see also e.g., Bayesian Statistics). Given data $\mathbf{d}$, we update these uncertainties using Bayes's rule

$$p(\mathbf{s}|\mathbf{d}) \propto p(\mathbf{s})\, p(\mathbf{d}|\mathbf{s}) = p(\mathbf{s}) \int p(\mathbf{d}|\boldsymbol{\theta}_s, \mathbf{s})\, p(\boldsymbol{\theta}_s|\mathbf{s}) d\boldsymbol{\theta}_s \qquad [6]$$

where $p(\mathbf{d}|\mathbf{s})$ is the marginal likelihood of the data given the model structure. Given the posterior uncertainties, we can either 'construct' a single DAG model by – say – selecting the most likely structure, or average over some or all of the model structures.

Under the assumptions described above – (1) mutual independence of the parameters in $\boldsymbol{\theta}_s$, (2) complete data, and (3) local distributions from the exponential family – the marginal likelihood can be computed efficiently and in closed form (e.g., Heckerman and Geiger, 1995). Furthermore, simple heuristic search methods, such as greedy hill climbing, can be used to find a structure whose posterior is relatively large. In applications where computational efficiency is important such as data mining, where both the number of domain variables and the number of data samples is large, these techniques are used extensively (Heckerman, 1996).

There are several non-Bayesian methods for learning structure from data. One set of techniques mimics Bayesian model selection, but incorporates non-Bayesian criteria for selection such as Akaike's information criterion (AIC). Another, developed independently by Pearl (2000) and Spirtes et al., (2001) uses local non-Bayesian tests for conditional independence together with search to identify model structures compatible with the data.

Pointers to the Literature

Perhaps the first person to use DAG models was Wright (1921), who employed what are now called structural equation models for the analysis of crop failure. Good (1961) also developed the representation. In both cases, researchers attributed causal semantics to DAG models. In fact, this model class remains quite popular for encoding and reasoning about causal interactions (Glymour and Cooper, 1999; Pearl, 2000; Spirtes et al., 2001; see also Latent Structure and Causal Variables).

In addition to directed models, researchers have developed and used graphical models containing undirected edges, bidirectional edges, and mixtures of directed and undirected edges (e.g., Wermuth, 1976; Whittaker, 1990; Lauritzen, 1996; Jordan, 1998).

Finally, there are numerous software packages available for the knowledge-based and data-based construction of DAG models. A summary is provided at http://http.cs.berkeley.edu/murphyk/Bayes/bnsoft.html.

Bayesian Models in Neuroscience

Abstract

The last two decades have seen a revolution in the statistical sciences with classical inferential approaches becoming slowly replaced by Bayesian ones. This has impacted on many fields in science and engineering, including neuroscience. A Bayesian perspective on neuroscience includes the idea that human behavior in many domains is close to statistical optimality and that the structure and machinery of the brain itself is reflected in message-passing algorithms that implement Bayesian inference.

This article presents a review of Bayesian models in Neuroscience. The work in this field splits broadly into two categories: (1) Bayesian modeling of behavior, which develops normative behavioral models based on statistical optimality principles, and (2) Bayesian models of the brain, which describe the internal operations of the brain that would give rise to such behaviors. In the latter category, neuroscientific data from a variety of sources are used including invasive electrophysiological recordings from mice, rats, and monkeys. It also focuses on detailed neurophysiological mechanisms over a range of spatial scales, from plasticity in dendrites to changes in connectivity among brain regions. Given the nature of this encyclopedia, our review focuses most strongly on the former category (behavior), as this is more closely related to psychology and sociology.

The review is structured in two main sections. The first section provides a mathematical description of Bayesian inference, introducing the basic concepts that will be referred to later on. We use the example of a game of tennis to make the main ideas more concrete. The second section reviews Bayesian models of behavior, focusing on a range of topics. Under 'sensory integration,' we review how, for example, information from visual and tactile senses are optimally combined. Under 'visual processing,' we review models of visual search and the processing of ambiguous or conflicting visual information. Under 'sensorimotor integration,' we describe how dynamic Bayesian models accurately describe how the consequences of movements can be predicted and perceptually downweighted. Under 'collective decision making,' we review how Bayesian inference has been used to describe how groups of people interact to make decisions.

Bayesian Inference

Consider some quantity, x. Our beliefs about the likely values of x can be described by the probability distribution $p(x)$. If we make a new observation y that is related to x, then we can update our belief about x using Bayesian inference. In statistics the optimal way of updating your beliefs is via Bayes rule.

First we need to specify the likelihood of observing y given x. This is specified by a probability distribution called the likelihood, $p(y|x)$. It tells us, if we know x, what are the likely values of y. Our updated belief about x, that is, after observing the new data point y is given by the posterior distribution $p(x|y)$.This can be computed via Bayes rule:

$$p(x|y) = \frac{p(y|x)p(x)}{p(y)} \qquad [1]$$

The denominator ensures that $p(x|y)$ sums to 1 over all possible values of x, i.e., that it is a probability distribution. It can be written as

$$p(y) = \int p(y|x')p(x')\mathrm{d}x' \qquad [2]$$

Equations [1] and [2] describe the basic computations underlying Bayes rule. These are multiplication and normalization (eqn [1]) and marginalization (eqn [2]). Following Wolpert and Ghahramani (2004), we will use the game of tennis to illustrate key points. Imagine that you are receiving serve. One computation you need to make before returning serve is to estimate x, the position of the ball when it first hits the ground, as depicted in **Figure 1**.

It is possible to make an estimate solely on the basis of the balls trajectory, i.e., via the data y. We can find the value of x which maximizes the likelihood, $p(y|x)$. This is known as Maximum Likelihood (ML) estimation. It is also possible to

Figure 1 Estimating the position of the ball when it first lands. The prior is shown in blue, the likelihood distribution in red, and the posterior distribution with the white ellipse. The maximum posterior estimate is shown by the magenta ball. This estimate can be updated in light of new information about the ball's trajectory (yellow). Adapted from Wolpert, D., Ghahramani, Z., 2004. Bayes rule in perception, action and cognition. In: Gregory, I.L. (Ed.), Oxford Companion to the Mind. Oxford Univ.

estimate the uncertainty in this estimate. The ML estimate and the uncertainty in it together give rise to the likelihood distribution shown in Figure 1.

But before our opponent hits the ball we may have a good idea as to where they will serve. It may be the case, for example, that when they serve from the right the ball tends to go down the line. We can summarize this belief by the prior distribution $p(x)$ (shown in blue in Figure 1). We can then use Bayes rule to estimate the posterior distribution. This is the optimal combination of prior knowledge ('down the line') and new data (visual information from the ball's trajectory). Our final single best estimate of where the ball will land is then given by the maximum of the posterior density. This is known as MAP estimation (from 'Maximum a Posteriori').

As we continue to see the ball coming toward us we can refine our belief as to where we think the ball will land. This can be implemented by applying Bayes rule recursively such that our belief at time point n depends only on our belief at the previous time point, $n-1$. That is,

$$p(x_n|Y_n) = \frac{p(y_n|x_n)p(x_n|Y_{n-1})}{p(Y_n)} \quad [3]$$

where $Y_n = \{y_1, y_2, \ldots, y_n\}$ denotes all observations up to time n. Our prior belief, that is, prior to observing data point y_n is simply the posterior belief after observing all data points up to time $n-1$, $p(x_n|Y_{n-1})$. Colloquially, we say that "today's prior is yesterday's posterior."

The variable x is also referred to as a hidden variable or hidden state because it is not directly observed. If the hidden state were a discrete variable, such as whether the ball landed in or out of the service box, one can form a likelihood ratio:

$$\mathrm{LR} = \frac{p(x_n = \mathrm{IN}|Y_n)}{p(x_n = \mathrm{OUT}|Y_n)} \quad [4]$$

Decisions based on the likelihood ratio are statistically optimal in the sense of having maximum sensitivity for any given level of specificity. In contexts where LR is recursively updated, these decisions correspond to a sequential likelihood ratio test (Bogacz et al., 2006). There is a good deal of evidence showing that the firing rate of single neurons in the brain report evolving log LR values (Gold and Shadlen, 2001).

Gaussians

If our random variables x and y are normally distributed, then Bayesian inference can be implemented exactly using simple formulae. These are most easily expressed in terms of precisions, where the precision of a random variable is its inverse variance; a precision of 10 corresponds to a variance of 0.1. We first look at inference for a single variable (e.g., distance from side of tennis court).

For a Gaussian prior with mean m_0 and precision λ_0 and a Gaussian likelihood with mean m_d and precision λ_d, the posterior distribution is Gaussian with mean m and precision λ where

$$m = \frac{\lambda_0}{\lambda} m_0 + \frac{\lambda_d}{\lambda} m_d \quad [5]$$

So, precisions add and the posterior mean is the sum of the prior and data means, but each weighted by their relative precision. This relationship is illustrated in Figure 2. Though fairly simple, eqn [5] shows how to optimally combine two sources of information. As we shall see in the following section, various aspects of human behavior from sensory integration to instances of collective decision making have been shown to conform to this 'normative model.' Similar formulae exist for multivariate (instead of univariate) Gaussians (Bishop, 2006) where we have multidimensional hidden states and observations, e.g., three-dimensional position of the ball, and two-dimensional landing position on court surface.

Figure 2 Bayes rule for Gaussians. For the prior $p(x)$ (blue) $m_0 = 20$, $\lambda_0 = 1$ and the likelihood $p(y|x)$ (red) $m_d = 25$, $\lambda_d = 3$, the posterior $p(x|y)$ (magenta) shows the posterior distribution with $m = 23.75$, $\lambda = 4$. The posterior is closer to the likelihood than the prior because the likelihood has higher precision. Bayes rule for Gaussians has been used to explain many behaviors from sensory integration to collective decision making.

Behavioral Models

An attractive feature of Bayesian models of behavior is that they provide descriptions of what would be optimal for a given task. They are often referred to as 'ideal observer' models because they quantify how much to update our beliefs in light of new evidence. Departures from these normative models can then be explained in terms of other constraints such as computational complexity or individual differences.

One way to address individual differences is to use an empirical Bayesian approach in which parameters of priors and their parametric forms are estimated from data. See Stocker and Simoncelli (2006) for an example of this approach in modeling visual motion processing.

What follows is a review of Bayesian models of sensory integration, visual processing, sensorimotor integration, and collective decision making. As we shall see, the priors that we have about, for example, our visual world most readily show themselves in situations of stimulus ambiguity or at low signal-to-noise ratios. Much of the phenomonology of these perceptual illusions is long established (Gregory, 1998) but Bayesian modeling provides new quantitative explanations and predictions. A more introductory review of much of this

material is available in Frith's outstanding book on mind and brain (Frith, 2007).

Sensory Integration

Ernst and Banks (2002) considered the problem of integrating information from visual and tactile (haptic) modalities. If vision v and touch t information are independent given observation of an object x, then Bayesian fusion of sensory information produces a posterior density:

$$p(x|v,t) = \frac{p(v|x)p(t|x)p(x)}{p(v,t)} \quad [6]$$

For a uniform prior $p(x)$ and for Gaussian likelihoods, the posterior will also be a Gaussian with precision λ_{vt}. From Bayes rule for Gaussians (eqn [5]), we know that precisions add:

$$\lambda_{vt} = \lambda_v + \lambda_t \quad [7]$$

where λ_v and λ_t are the precision of visual and haptic senses alone, and the posterior mean is a relative-precision weighted combination:

$$m_{vt} = w_v m_v + w_t m_t \quad [8]$$

where the weights are $w_v = \lambda_v/\lambda_{vt}$ and $w_t = \lambda_t/\lambda_{vt}$.

Ernst and Banks (2002) asked subjects which of two sequentially presented blocks was the taller. Subjects used either vision alone, touch alone or a combination of the two. They recorded the accuracy with which discrimination could be made and plotted this as a function of difference in block height. This was repeated for each modality alone and then both together. They also used various levels of noise on the visual images. From the single modality discrimination curves they then fitted cumulative Gaussian density functions, which provided estimates of the precisions λ_t and $\lambda_v(i)$ where i indexes visual noise levels.

In the dual modality experiment, the weighting of visual information predicted by Bayes' rule for the ith level of visual noise is

$$w_v(i) = \frac{\lambda_v(i)}{\lambda_v(i) + \lambda_t} \quad [9]$$

This was found to match well with the empirically observed weighting of visual information. They observed visual capture (strong weighting) at low levels of visual noise and haptic capture at high levels. Inference in this simple Bayesian model is consistent with standard signal detection theory. However, Bayesian inference is more general as it can accommodate, for example, nonuniform priors over block height.

There have been numerous studies of the potential role of Bayesian inference for integration of other senses. For example, object localization using visual and auditory cues (Alais and Burr, 2004) has supported a Bayesian integration model with vision dominating audition in most ecologically valid contexts. This visual capture is the basis of the 'ventriloquism' effect, but is rapidly degraded with visual noise. This literature has considered only simple inferences about single variables such as block height or spatial location. Nevertheless these studies have demonstrated a fundamental concept; that sensory integration is near Bayes-optimal.

The representations in the brain that are used to support the above computations are a subject of ongoing study. One proposal is that populations of neurons represent probability distributions such that higher neuronal firing rates reflect higher precisions. Moreover, if the distribution of cell activities is approximately Poisson then Bayesian inference for optimal cue integration, for example, can be implemented with simple linear combinations of neural activity (Ma et al., 2006). Recent recordings in which monkeys were trained to estimate direction of motion from visual and vestibular cues showed neuronal activity consistent with this theory (Fetsch et al., 2011).

Visual Perception

Kersten et al. (2004) reviewed the problem of visual object perception and argued that much of the ambiguity in visual processing, for example concerning occluded objects, can be resolved with prior knowledge. This idea is naturally embodied in a Bayesian framework (Knill and Richards, 1996) and has its origins in the work of Helmholtz who viewed perception as 'unconscious inference.' An example is how the inference of shape from shading is informed by a 'light-from-above' prior. This results in circular patches that are darker at the bottom being perceived as convex. The adaptability of this prior, and subsequent perceptual experience, has been demonstrated by Adams et al. (2004).

An example of such a Bayesian modeling approach is the work of Yu et al. (2009) who propose a normative model for the Eriksen Flanker task. This simple decision-making task was designed to probe neural and behavioral responses in the context of conflicting information. On each trial, three visual stimuli are presented and subjects are required to press a button depending on the identity of the central stimulus. The flanking stimuli are either congruent or incongruent. Yu et al. (2009) proposed a discrete time ideal observer model that qualitatively captured the dynamics of the decision-making process. This used the recursive form of Bayes rule in eqn [3]. In later work, a continuum time limit of this model was derived, which produced semi-analytic predictions of reaction time and error rate that accurately predicted subject behavior. They also proposed an algorithm for how these models could be implemented in the brain.

Weiss et al. (2002) proposed that many motion illusions arise from the result of Bayes-optimal processing of ecologically invalid stimuli. Their model was able to reproduce a number of psychophysical effects based on the simple assumptions that measurements are noisy and the visual system has a prior which expects slower movements to be more likely than faster ones. For example, the model could predict the direction of global motion of simple objects such as rhomboids, as a function of contrast and object shape. This model was later refined (Stocker and Simoncelli, 2006) by showing the prior to be non-Gaussian and subject specific, and that measurement noise variance was inversely proportional to visual contrast.

Najemnik and Geisler (2005) developed an ideal Bayesian observer model of visual search for a known target embedded in a natural texture. Prior beliefs in target location were updated to posterior beliefs using a likelihood term that reflected the foveated mapping properties of visual cortex. When this likelihood was matched to individual subjects discrimination

ability, the resulting visual searches were nearly optimal in terms of the median number of saccades. Later work showed that fixation statistics were also similar to the ideal observer.

An important idea to emerge in recent years is that Bayesian inference operates at the level of cortical macrocircuits (Rao and Ballard, 1999). These circuits are arranged in a hierarchy that reflects the hierarchical structure of the world around us, e.g., scenes are comprised of objects that are in turn comprised of features that are in turn comprised of simpler elements. The connections among regions have also been proposed to have a rather specific anatomy. For example, top-down connections originate from cortical pyramidal cells lying deep in the gray matter (i.e., close to white matter) whereas bottom-up connections originate more superficially (Mumford, 1992). The signals sent up and down these cortical hierarchies then map onto the message-passing algorithms that implement Bayesian inference in dynamic, hierarchical models (Friston, 2003).

If the world we perceive is the result of hierarchical processing in cortical networks then, because this processing may take some time (of the order of 100 ms), what is perceived to be the present could actually be the past. As this would be disadvantageous for the species, it has been argued that our perceptions are based on predictive models. A 50 ms delay in processing could be accommodated by estimating the state of the world 50 ms in the future. There is much experimental evidence for this view (Nijhawan, 1994). However, a purely 'predictive' account fails to accommodate recent findings in visual psychophysics. The flash-lag effect, for example, is a robust visual illusion whereby a flash and a moving object that are located in the same position are perceived to be displaced from one other. If the object stops moving at the time of the flash no such displacement is perceived. This indicates that the position of the object after the flash affects our perception of where the flash occurred. This 'postdictive' account explains the phenomenon (Eagleman and Sejnowski, 2000) and related data where the object reverses its direction at the flash time. A simple Bayesian model has been proposed to account for the activity of V4 neurons in this task (Sundberg et al., 2006) and later experimental work found evidence for a linear combination of both predictive and postdictive mechanisms.

Sensorimotor Integration

Wolpert et al. (1995) have examined the use of dynamic Bayesian models, also referred to as forward models, for sensorimotor integration. These models describe relations among a current state variable x_n, motor commands u_n, and sensory observations y_n. The state might correspond, for example, to a multivariate vector comprising a list of joint angle positions and velocities. These dynamic models have a transition density $p(x_n|x_{n-1}, u_{n-1})$ describing how the hidden state evolves over time. The posterior distribution over hidden states can then be computed as described in standard texts (Bishop, 2006). First, the dynamical equation describing state transitions is integrated to create an estimate of the next state. This requires as input a copy of the current motor command (so-called 'efference copy') and the current state. This is referred to as a time update step. A prediction of sensory input can then be made based on the predicted next state and the mapping from x_n to y_n. Finally, a measurement update or correction step can be applied, which updates the state estimate based on current sensory input.

Wolpert et al. (1995) cite a number of key features of dynamic Bayesian models including the following. First, they allow outcomes of actions to be predicted and acted upon before sensory feedback is available. This may be important for rapid movements. Second, they use efference copy to cancel the sensory effects of movement ('re-afference'), e.g., the visual world is stable despite eye movements. Third, simulation of actions allows for mental rehearsal which can potentially lead to improvements in movement accuracy.

This mathematical framework was applied to the estimation of arm position using proprioceptive feedback and a forward model based on a linear dynamical system (Wolpert et al., 1995). Inference in this model was then implemented using a Kalman filter. The resulting bias and variance in estimates of arm position were shown to closely correspond to human performance, with proprioceptive input becoming more useful later on in the movement when predictions from the forward model were less accurate.

One of the core ideas behind these forward models is that, during perceptual inference, the sensory consequences of a movement are anticipated and used to attenuate the percepts related to these sensations. This mechanism reduces the predictable component of sensory input to self-generated stimuli, thereby enhancing the salience of sensations that have an external cause. This has many intriguing consequences. For example, it predicts that self-generated forces will be perceived as weaker than externally generated forces. This prediction was confirmed in a later experiment (Shergill et al., 2003), thereby providing a neuroscientific explanation for force escalation during conflict; children trading tit-for-tat blows will often assert the other hit him harder.

Kording and Wolpert (2004) have investigated learning in the sensorimotor system using a visual reaching task in which subjects moved their finger to a target and received visual feedback. This feedback provided information about target position that had an experimentally controlled bias and variance. Subjects were found to be able to learn this mapping (from vision to location) and integrate it into their behavior in a Bayes-optimal way.

Returning to our tennis theme, an analysis of 3 years of Wimbledon games has indicated that the outcome of the current point depends on the outcome of the previous point (Klaassen and Magnus, 2001). There are multiple potential sources of correlation here. It could be that a player intermittently enjoys a sweet parameter spot where his internal sensorimotor model accurately predicts body and ball position and is able to hit the ball cleanly, or perhaps a player finds a new pattern in his opponent's behavior such as body position, or previous serve, predicting current service direction.

Collective Decision Making

Sorkin et al. (2001) have applied Bayes rule for Gaussians (see eqn [5]) in their study of collective decision making. Here the optimal integration procedure involves each group members' input to the collective decision being weighted proportionally by the member's competence at the task. Statistically, 'competence' corresponds to precision. This model

of group behavior was shown to be better than a different model which assumed members made individual decisions which were then combined into a majority vote. This latter model better described collective decision making when members did not interact.

Bahrami et al. (2010) investigated pairs of subjects (dyads) making collective perceptual decisions. Dyads with similarly sensitive subjects (similar precisions) were found to produce collective decisions that were close to optimal, but this was not the case for dyads with very different sensitivities. These observations were explained by a Bayes-optimal model under the assumption that subjects accurately communicated their confidence. This confidence sharing proved essential for the group decision to be better than the decision of the best subject.

Bayesian Statistics

Abstract

Bayesian statistics is an approach to statistical inference that is characterized by the use of probability distributions to describe the state of knowledge about unknown quantities and the use of Bayes' theorem to update the state of knowledge to account for observed information. The basic ideas date to the late eighteenth century but broad application of the approach did not occur until computational developments in the late twentieth century allowed for simulation-based inference in a wide range of scientific applications. This article describes the key steps in carrying out a Bayesian analysis: model specification, calculation of the posterior distribution, and model assessment.

Bayesian statistics refers to an approach to statistical inference that is characterized by the use of probability distributions to describe the state of knowledge or belief about unknown quantities (e.g., parameters in a statistical model) and the updating of such distributions based on observed information (e.g., data). The approach takes its name from the use of Bayes' theorem (Bayes and Price, 1763), a mathematical result relating conditional probabilities, to perform the updating of probability distributions. As commonly practiced there are three key steps in a Bayesian analysis: specification of a probability model for the quantities of interest, calculation of the posterior distribution of unknown quantities conditional on observed quantities, and assessment of the appropriateness of the model for the questions at hand. These are discussed in detail below. The last of these topics, model assessment, is not always incorporated in introductory discussions of Bayesian statistics but it is argued below that it is an essential part of good statistical practice. Naturally, the discussion of the Bayesian approach here is brief. Additional details can be found in a wide range of modern statistical treatments including Carlin and Louis (2008), Christensen et al. (2010), and Gelman et al. (2013).

It is useful to begin with a brief history of the development of Bayesian ideas. Early work on probability focused on what might be called 'pre-data' probability calculations. Given assumptions about a random process, it is possible to assign or calculate the probability of various outcomes. For example, one can calculate the probability of obtaining an even number in a roll of a die or the probability of obtaining 10 or more heads in 20 tosses of a coin. Bayes and Laplace receive independent credit for 'inverting' probability statements in the late eighteenth century to make probability statements about parameter values given observed data values (Stigler, 1986). Thus, for example, having observed a given number of successes in a series of repeated trials, it is possible to make probability statements about the unknown probability of success in the trials. Modern Bayesian inference developed in the period around and after World War II. The name Bayesian inference replaces 'inverse probability' only in this era. Savage (1954) is an influential early book using decision theory to justify Bayesian methods. de Finetti (1974) contributed crucial work concerning the role of exchangeability, which plays a role analogous to that of independent identically distributed observations in the traditional frequentist approach to inference. Raiffa and Schlaifer (2000), Lindley (1972, 1990), and Box and Tiao (1973) contributed greatly to the popularization of the Bayesian approach. Computational advances in the late twentieth century, especially the development of fast, ubiquitous computers and the discovery (and rediscovery) of computational algorithms, made it possible to apply the Bayesian approach to a wide array of scientific fields and scientific problems. Indeed, one can now find Bayesian treatments for a variety of different application areas including the social sciences (Jackman, 2009), econometrics (Koop et al., 2007), marketing (Rossi et al., 2006), and biostatistics (Lesaffre and Lawson, 2012).

Model Specification

The basic ideas needed to describe Bayesian statistics can be easily explained in terms of some relatively simple notation. Let y denote data that is to be collected, such as a series of measurements or the outcomes of a series of test questions. Take θ to denote unknown quantities associated with the collection of the data. Often, θ represents the parameters in a probability model for the data y. This could include the mean measurement of a population of interest or the true ability of an individual test taker. There are of course many situations that are not adequately represented by this simple setup. For example, in some cases, like regression analysis, there may be data x (often called covariates) that can help explain y but are not of explicit interest themselves. Sometimes the unknown θ may include missing values (data that were intended to be collected but could not) or latent variables (additional unknowns introduced in developing a probability model) in addition to standard parameters. Here the simple notation y and θ are used throughout but it is straightforward to accommodate more complex situations like those described above. For details, see the references provided earlier.

The specification of a complete probability model for the data y requires two probability distributions: a probability distribution for the data given (or conditional) on parameters θ and a probability distribution for the parameters θ. The distribution of the data conditional on the parameters is usually denoted $p(y|\theta)$ and identified as the data distribution,

the data model, the sampling distribution, or the likelihood function. The distribution for the parameters θ, denoted $p(\theta)$, is known as the prior distribution. It can be thought of as describing the relative frequencies for different values of the model parameters before considering any of the data values. The notation above violates standard conventions in that the same letter p is used to represent two different probability distributions. It is useful for the purposes discussed here, however, in that it avoids the introduction of other letters that are not central to this discussion. The notation above is simple but is capable of accommodating the full range of Bayesian methods. For example, it is sometimes desirable to avoid specific parametric forms for one or both of the component distributions. The development of so-called nonparametric Bayesian methods has made this possible; in practice, they are still of the form $p(y|\theta)$ and/or $p(\theta)$ but rely on high-dimensional θ to avoid being overly restrictive in the choice of the distribution $p(.)$.

A simple example helps to show how the basic notation works. Suppose that a student is asked to answer a number of mathematics questions believed to measure his or her knowledge of algebra. Assuming there are n questions believed to be of roughly the same level of difficulty, it may be natural to let the number of correct responses y follow a binomial distribution with parameter θ measuring the probability that the student answers a question correctly (which can be taken as a measure of their knowledge of algebra). Then $p(y|\theta)$ is the binomial probability of getting exactly y correct responses, $\binom{n}{y}\theta^y(1-\theta)^{n-y}$. The prior distribution $p(\theta)$ should reflect any information about θ that is available prior to collecting the data. This choice is discussed further next.

For many users of statistical methods, the largest question about the use of Bayesian methods concerns the choice of prior distribution. There are a number of approaches to this choice. The subjective approach to choosing a prior distribution is to take the prior distribution to be an honest assessment of prior beliefs about the values of the model parameters. Although people are sometimes hesitant to supply such subjective prior distributions, it is often the case that some prior information is available. For the example discussed, a great deal may not be known about the specific student but previous experience may suggest that typically students in the class are able to answer between 60 and 90% of such questions correctly. This may be enough to suggest a prior distribution such as a beta distribution (appropriate for quantities that take values between 0 and 1) with parameters 3 and 1, which takes the form $p(\theta) = 3\theta^2$. This beta distribution has a mean of 0.75 with about half of the probability in the interval from 0.60 to 0.90. If it is possible to specify a prior distribution, like the beta distribution suggested here, then the Bayesian paradigm provides the way to update that prior information given observed data. The updating is discussed below.

Occasionally, the choice of a prior distribution is made primarily because of considerations of computational convenience. Conjugate families are families of prior distributions that combine with a given data distribution to produce posterior distributions in the same family as the prior distribution. The beta distribution developed above is an example; it is the conjugate prior distribution for binomial data. Conjugate prior distributions are capable of supporting a variety of prior opinions (e.g., by making different choices within the conjugate family) but of course not all.

The desire to avoid using subjective prior information and/or arbitrary distributional forms has led to research on using vague or 'noninformative' prior distributions. Formally, a vague prior distribution is one that assigns roughly equal probability to a wide range of possible values. In the binomial example, it might be asserted that there is no information at all about θ other than that it is between 0 and 1 and thus a uniform distribution between 0 and 1 may be chosen. (In fact, this is a particular form of the beta distribution.) The idea is that a vague prior distribution will not have a strong influence on the results and that the data will play the central role in determining the conclusions. In this way, the use of vague or 'noninformative' prior distributions represents the pursuit of a form of objective Bayesian inference. One difficulty is that, in the limit, especially for parameters that are not known to lie in a fixed range, vague prior distributions may become so vague as to no longer be proper distributions (they may not integrate to one!). It is 'legal' to use such improper prior distributions as long as it is verified that the resulting posterior distribution is a proper distribution. Improper prior distributions are popular because sometimes they appear to be 'noninformative' in the sense that they rely only on the likelihood. It is probably best to think of improper prior distributions as approximations to real prior distributions. If the improper prior distribution leads to a proper posterior distribution and sufficiently accurate conclusions, then one might use the results from this analysis without needing to work any harder to select a more appropriate prior distribution.

Some people find the need to explicitly choose a prior distribution problematic. For these individuals, it is disturbing that individuals with different prior distributions will obtain different results. There are a number of important points to make here. First, it is important to recognize that situations like this occur every day in the real world when individuals with different information make different decisions from the same data. Second, it is possible to show mathematically that the prior distribution does not have a large impact on the results of the statistical analysis when a great deal of data has been collected. This again matches everyday experiences where a large group of people may all come to agree on a course of action given a large amount of evidence. Perhaps the most important point to make is that prior information is not necessarily as rare as might be thought. This is especially true in problems that are more sophisticated than the simple math test. Consider a situation in which the same set of algebra questions are given to a number of different individuals. Each individual has his or her own probability of getting a correct answer. Although it may not be easy to select a prior distribution for each individual, it may be natural to treat the set of parameters as a sample from a common population. This type of model is known as a hierarchical model (*see* Hierarchical Models: Random and Fixed Effects) because the prior distribution itself may depend on additional parameters (e.g., the mean and variance of algebra knowledge parameters in the population). It is the success of Bayesian methods in multiparameter problems of this type that has led to the increased use of such methods.

Calculation of the Posterior Distribution

The model specification makes it clear that there are two sources of information about θ. There is information about θ in the prior distribution and there is information about θ in the data distribution. This information can be combined using the laws of probability, namely, Bayes' theorem, to obtain the updated probability distribution on θ after observing data y. The latter is known as the posterior distribution of θ and denoted $p(\theta|y)$. Bayes' theorem is

$$p(\theta|y) = p(y|\theta)p(\theta)/p(y) = p(y|\theta)p(\theta) \Big/ \int p(y|\theta)p(\theta)\mathrm{d}\theta$$

The denominator of Bayes' theorem is known as the marginal probability of observing the data y. Bayes' theorem allows one to update his or her opinion about the possible values of θ so that values of θ that are most consistent with the observed data (i.e., values that have large values of the likelihood) have more weight in the posterior distribution then they do in the prior distribution.

The posterior distribution is fundamental to Bayesian inference for θ. The Bayesian approach makes probability statements concerning the unknown quantities after fixing the things that have been observed (i.e., the data) at their known values. Note that Bayesian methods differ from traditional methods, which are justified by repeated sampling considerations – only the sample at hand is considered relevant in the Bayesian approach.

The posterior distribution describes the current state of knowledge about θ after observing the data y. It is possible to draw a wide range of inferential conclusions from the posterior distribution. A point estimate is a one-number summary of the posterior distribution. Of course, a single estimate does not describe the full state of knowledge. To obtain a point estimate, it is necessary to specify a loss function that makes explicit the loss that is expected to be incurred because of errors in the point estimate. Given a loss function, it is possible to derive the optimal point estimate as the value that minimizes the expected loss (computed from the posterior distribution). An interval estimate specifies a range of plausible values for a parameter. The posterior distribution allows one to identify posterior intervals that contain a given parameter with any specified probability. Such intervals are analogous to standard confidence intervals. One difference is that the posterior intervals have a natural probabilistic interpretation in that they summarize the posterior state of knowledge regarding plausible values of the parameter. By contrast, the probability statements underlying traditional confidence intervals depend on behavior in a large number of repeated samples. In traditional inference, another common form of statistical inference is a hypothesis test about the value of a parameter or a set of parameters (e.g., it is common to test whether two means are equal). The information about such tests is equivalent to the information contained in posterior intervals, i.e., it can be addressed whether two means are plausibly the same by examining the posterior interval for the difference between the two means. Tests of some hypotheses are also possible using the Bayes factor, a ratio that measures the degree to which two competing models explain the observed data. This is discussed further below.

In relatively simple problems it is possible to analytically determine the form of the posterior distribution and subsequently obtain statistical inferences. For the example described earlier in which a binomial random variable measuring the number of correct responses y in n questions was observed and a conjugate beta prior distribution was used (with parameters 3 and 1), it turns out that the posterior distribution is also a beta distribution. The posterior distribution is a beta distribution with parameters $y + 3$ and $n - y + 1$. The form of the posterior distribution in this case shows explicitly how prior information combines with the data. The mean of this posterior distribution is $(y + 3)/(n + 4)$, which is a compromise between the students performance on the test y/n and the mean of the prior distribution $3/4 = 0.75$. For example, a student who answered 9 of 10 questions correctly would have posterior mean 0.86. Posterior intervals can also be easily obtained if the form of the posterior distribution is known.

In many realistic models, especially those containing a large number of parameters, it can be quite difficult to determine the form of the posterior distribution analytically. It is sometimes possible in such cases to develop a useful approximation to the posterior distribution, e.g., a normal approximation, but this too is difficult in many realistic problems. For many years, the difficulty in calculating the posterior distribution kept people from applying Bayesian methods. The wide availability of high-speed computing, beginning in the late twentieth century, made it possible to develop general-purpose simulation algorithms that allowed researchers to approximate the posterior distribution by generating a sample of simulations from the posterior distribution. The most common class of algorithms are known as Markov chain Monte Carlo (MCMC) algorithms; these algorithms work by building and then simulating a Markov chain, which has the posterior distribution as its stationary distribution. If the Markov chain is simulated for a long time, then the draws from the simulation can be treated as draws from the posterior distribution. Although there can be a number of challenges associated with Bayesian computation (e.g., developing efficient algorithms, judging when the simulation has run long enough to approximate the posterior distribution), there is little doubt that it has allowed researchers to apply Bayesian methods in diverse settings and with large data sets. Recent references describing MCMC algorithms and other relevant computational strategies include Chen et al. (2001), Liu (2008), and Brooks et al. (2011).

Simulation-based inference is a powerful tool. A set of simulations from the posterior distribution provides an empirical approximation to the posterior distribution. Any desired inference is then estimated using this empirical approximation. For example, the posterior mean is estimated by the sample mean of the simulations and a posterior interval for a parameter is obtained using the relevant percentiles of the simulations. Although the simulations are in fact providing estimates of the various quantities of interest, it is generally possible to obtain enough simulations to reduce the Monte Carlo or simulation error to acceptable levels. Simulations provide a great deal of flexibility – for example, it is

quite straightforward to estimate the posterior probability that a given parameter is positive since one needs only to calculate the proportion of simulations in which it is positive.

Model Assessment

It is important when performing statistical inference based on a probability model to examine the validity of the assumptions made in the model. For the Bayesian approach to inference, the assumptions include the form of the prior distribution, the form of the data model, and any other assumptions embodied in the data model (independence, constant variance, etc.). There are a wide range of activities that are useful for assessing the Bayesian model being used in a given situation. These include sensitivity analysis, model checking, and model comparison. Brief descriptions of these approaches are provided here. The general references provided earlier give additional details.

Sensitivity Analysis

The prior distribution is an important part of the Bayesian model. One can argue that there is no need to check the prior distribution in that as long as it is an honest reflection of the prior state of knowledge about unknown quantities, the Bayesian machinery will provide the appropriate updated posterior state of knowledge. At the same time, it is important to be able to describe whether the inferences are likely to change under other reasonable prior distributions. This suggests a form of sensitivity analysis where the prior distribution (or other aspect of the model) is varied and the effect on the posterior distribution is assessed. The conclusions of a Bayesian analysis are strengthened if it is found that key posterior inferences (e.g., the sign of an important parameter) are unchanged under other plausible model specifications.

Model Checking

In regression analysis, it is common to check the form of the model by examining residuals. The residuals are functions of the data that are expected to have no particular structure if the model is correct. Evidence of structure in the residuals suggests a possible problem with the model. The same basic strategy can be applied more generally to assess the fit of a Bayesian model or analysis. A function of the data (and perhaps parameters) can be defined that is expected not to have any structure if the model is correct. Examining the posterior predictive distribution of such functions (i.e., the distribution of the function in future data sets that would be expected if the model is correct) can allow one to detect difficulties in the model. These are known as posterior predictive model checks.

Model Comparison

In some applications, there are a number of models that are contemplated. In this case, researchers may want to compare or combine the models. Model comparison is frequently carried out using Bayes factors (*see* Model Selection and Model Averaging). It can also be carried out using predictive measures (e.g., cross-validation) or information criteria. There are several important points here. If model selection is used to identify a best-fitting model, it is still important to use model checking and sensitivity analysis as described above to ensure that the selected model is appropriate for the questions of interest. Also, one can argue that there are alternatives to model comparison and model selection that make more sense in the Bayesian framework. It may be possible to embed one model into a bigger family of models and then average over the entire family. For example, a normal model might be replaced by the Student-t family of models that includes the normal distribution as a limiting case. Then the posterior distribution for the degrees of freedom in the Student-t model provides information about whether the normal distribution is an appropriate choice.

Summary

The Bayesian approach to statistics outlined here is now used extensively in a wide range of application areas, including the social sciences. Historically, there has been controversy about the use of Bayesian methods. This remains true to a limited extent (Efron, 1986). The arguments favoring the use of the Bayesian approach for data analysis follow from its use of probability distributions to describe uncertainty about unknown quantities. There is a natural probability-based interpretation for Bayesian results (e.g., interval estimates) and great flexibility in the types of inferences that can be obtained (e.g., one can easily obtain a posterior distribution on the ranks of a set of parameters). In addition, the framework is extremely powerful in its ability to accommodate increasing degrees of complexity in a data analysis. For example, accommodating missing data values is straightforward in the Bayesian framework because the missing values become unknown random variables. In the same vein, censoring or truncation of observed values are easily incorporated through modifications of the underlying probability model. The reliance on formal probability distributions also means that it is possible to draw valid Bayesian inferences in finite samples without relying on large sample results.

Abstract

Bayes' theorem is a simple method for reversing conditional probabilities in straightforward probability problems. The theorem's application was expanded to become a full-fledged paradigm of statistics that provides a coherent, but subjective, method for updating scientific knowledge. For more than a century, Bayesian methodology was controversial in academia but used extensively in practical applications in the military and business. Improved computing capabilities, coupled with advances in estimation methods and increased applicability to contemporary statistical problems have made it a mainstream methodology. In recent years, Bayesian applications have become too numerous to discuss in detail. Instead, general directions are discussed.

Introduction

Bayesian statistics is an approach to – or paradigm of – statistics that involves updating prior beliefs with new data, or more succinctly, 'learning' from data. Contemporary Bayesian statistics takes a subjective view of probability; that is, Bayesians argue that probability represents uncertainty, and therefore the language of probability can be used to represent any quantity that is unknown, including model (or distribution) parameters, even if such a quantity is, in fact, fixed. As more data are gathered, we can update our knowledge of the quantity of interest until, in theory, we eventually can learn its true (or current) value. This perspective on probability contrasts with the more classical view that data are random realizations of a process governed by a fixed parameter, that probabilistic language can only represent random quantities, and so probability distributions cannot be used to represent parameters.

Versions of Bayes' Theorem

Bayesian statistics begins with Bayes' theorem, which is simply a rule for reversing conditional probabilities. Using discrete sample spaces, Bayes' rule can be represented as:

$$p(\mathrm{B}|\mathrm{A}) = \frac{p(\mathrm{A}|\mathrm{B})p(\mathrm{B})}{p(\mathrm{A})} \qquad [1]$$

In this equation, $p(\mathrm{B}|\mathrm{A})$ is the probability of event B, given that we know event A has occurred, $p(\mathrm{A}|\mathrm{B})$ is the probability that event A occurs given that we know event B occurred, $p(\mathrm{B})$ is the probability that event B occurs, and $p(\mathrm{A})$ is the total probability of event A. In a simple case in which there are two possible states of the world, B and not B, $p(\mathrm{A}) = p(\mathrm{A}|\mathrm{B})p(\mathrm{B}) + p(\mathrm{A}|\neg\mathrm{B})\,p(\neg\mathrm{B})$. In the more general case in which there are multiple possible states of the world,

$$p(\mathrm{A}) = \sum p(\mathrm{A}|\mathrm{B}_i)p(\mathrm{B}_i), \qquad [2]$$

where B_i indicates one of the possible states of the world, $p(\mathrm{B}_i)$ is its probability of occurrence, and $\Sigma p(\mathrm{B}_i) = 1$.

As a contrived, but concrete example of the application of Bayes' rule, suppose I am interested in computing the probability that a weaker-than-average student cheated off an 'A' student on a weekly quiz, given that he received an A on the quiz. Suppose that I have given a total of 10 quizzes prior to the current one, and this average student has made an A on only two of them. Also suppose that, if the student cheats, there is a probability of .9 that he will obtain an A. Finally, suppose I thought, prior to the exam, that there is only about a 10% chance that the student would cheat. So, 'B' is 'cheated' and 'A' is 'received an A on the exam.' The table below shows the information we have for computing the desired probability.

Term in Bayes' rule	*Meaning*	*Probability*
$p(\mathrm{A}\|\mathrm{B})$	Probability of earning an A if cheated	.9
$p(\mathrm{B})$	Prior probability of cheating	.1
$p(\mathrm{A}\|\neg\mathrm{B})$	Probability of earning an A if no cheating	.2
$p(\neg\mathrm{B})$	Probability of no cheating	.9

Substituting these quantities into Bayes' rule gives:

$$p(\mathrm{B}|\mathrm{A}) = \frac{(.9)(.1)}{(.9)(.1) + (.2)(.9)} = .333.$$

Thus, before this exam, my assumed 'prior' probability that the student would cheat was 1/10; after he received an A on the most recent exam, I think there is a probability of 1/3 that he cheated (this is called a 'posterior probability'). Why did my 'prior' probability increase so drastically? The reason is that, for that student, obtaining an A on an exam is uncharacteristic: based on previous exams, the probability that he would obtain an A is only .2. In contrast, the probability he would obtain an A if he cheated is rather high. Thus, the A provides more evidence for the position that he cheated than the position that he did not.

Bayes' theorem is easily proven, involving simply a double application of the joint probability rule: $p(\mathrm{A},\mathrm{B}) = p(\mathrm{A}|\mathrm{B})p(\mathrm{B})$. Given that $p(\mathrm{B},\mathrm{A}) = p(\mathrm{A},\mathrm{B})$, $p(\mathrm{B}|\mathrm{A})p(\mathrm{A}) = p(\mathrm{A}|\mathrm{B})p(\mathrm{B})$. Dividing both sides of this latter equality by $p(\mathrm{A})$ yields the theorem. The mathematics underlying the theorem is therefore indisputable. However, the theorem's use as a method for representing subjective beliefs and updating them via probabilistic language is controversial, and this controversy permeates the history of Bayesian statistics, as discussed below.

A Brief History

Bayes' theorem was developed by Reverend Thomas Bayes in the mid-1700s, albeit not in its modern symbolic representation. Bayes' initial motivation involved a thought experiment in which a billiard ball is thrown onto a table and its location marked. Then, another ball is thrown n times onto the table, and a record is kept reflecting the proportion of times the ball lands on each side of the original ball. The question is: how does each additional ball's position (i.e., the acquisition of new data) update our knowledge of where the initial ball landed? Bayes' paper on the topic was published posthumously in 1763 (Bayes died in 1761) by his friend and fellow Unitarian minister, Richard Price. Approximately half a century after Bayes wrote his seminal paper, Laplace rediscovered the theorem. From that time until more than a century later, the theorem was commonly known as 'inverse probability' in reference to the theorem's key contribution: the reversal of a conditional probability (de Finetti, 1974; McGrayne, 2011).

This theorem for point probabilities forms the basis of Bayesian statistics, but Bayesian statistics involves extending the components of the original theorem to handle more than single, point probabilities like that demonstrated in the previous section. First, the 'data' in the above example was the student's performance on a single quiz. In fact, however, we may have a series of quiz grades with which to update our prior belief that he or she cheats. In that case, the first term in Bayes' theorem may be replaced with a likelihood function – a joint distribution for quiz grades – rather than a single quiz grade. Second, depending on how well we know the student's history, say, in other courses, we would probably not be confident enough to assign an exact value of .1 as the prior probability of cheating. Instead, we may place a distribution on this prior probability that gives a (potentially) differential weight to different prior probabilities of cheating. For example, we may believe a priori that the student's probability of cheating is about .1, give or take a few percent, with higher and lower probabilities of cheating being less likely. The prior distribution, then, may be bell-shaped with a peak centered over the value .1. Bayes' theorem can therefore be extended to continuous sample spaces and probability distributions as:

$$f(\theta|\gamma) = \frac{f(\gamma|\theta)\, f(\theta)}{f(\gamma)}. \qquad [3]$$

In this equation, $f(\theta|\gamma)$ is the 'posterior' *distribution* of θ, given the data γ. $f(\gamma|\theta)$ is the *distribution* for γ, given θ – the likelihood function in classical terminology, $f(\theta)$ is the 'prior' *distribution* for θ, and $f(\gamma)$ is the marginal distribution for γ. Here, $f(\gamma) = \int_S f(\gamma|\theta) f(\theta) d(\theta)$, where S is the sample space for θ. This integral is simply the continuous analog to the summation presented in eqn [2]. It is worth reiterating that the product of two distributions – one for the prior and one for the likelihood – yields a distribution for θ, rather than a single point estimate for θ, and this distribution represents our updated level of knowledge (and uncertainty) about θ.

More important than the shift from discrete point probabilities to continuous probability distributions is that this representation of the theorem includes both data (γ) and probability distribution parameters (θ) rather than data alone. Assigning probability distributions to parameters essentially represents the degree of uncertainty we have regarding theoretical hypotheses about the nature of some phenomenon. Consider the example above. The 'prior' probability of .1 that the student cheated is essentially just a 'guess' about the student's propensity to cheat prior to my having observed any data. This guess may be informed by my previous experience with students or my experience with this particular student. But it is essentially a hypothesis. The posterior probability that the student cheated is a revision of that hypothesis that takes into account the new data – the A on the most recent test. Thus, we could rewrite Bayes' theorem as:

$$f(\text{Hypothesis}|\text{Data}) = \frac{f(\text{Data}|\text{Hypothesis})\, f(\text{Hypothesis})}{f(\text{Data})}, \qquad [4]$$

where f(Data) is the marginal probability distribution for the data under all possible hypotheses. Thus, this formulation of Bayes' theorem suggests that we can evaluate the probability of a hypothesis conditional on observed data. Furthermore, given that f(Data) generally contains no information regarding the hypothesis that is not contained in the numerator and is simply a normalizing constant that makes the posterior distribution a proper probability distribution, the theorem is often reduced to:

$$\text{Posterior} \propto \text{Likelihood} \times \text{Prior}, \qquad [5]$$

where '$\propto$' means 'is proportional to.'

This specification for Bayes' theorem has invoked the greatest criticism historically and relegated Bayesian statistics to a marginal status for decades, if not centuries. From a 'classical' statistics perspective, a parameter is a fixed, but generally unknown quantity, and therefore it makes no sense to place a probability distribution on a parameter (and therefore a scientific hypothesis). From that view, only data are random: a given sample is a stochastic realization from a distribution with fixed parameters. Under that approach, hypotheses about the true state of the world are assessed by (1) posing the hypothesis and (2) evaluating the likelihood of observing the sample data we in fact observed. If the data are unlikely to have occurred if the hypothesis were true, we conclude that the hypothesis is improbable (Fisher, 1960). Another way to view the classical criticism is that hypotheses and data cannot share the same sample space, and so it makes no sense to talk about the joint distribution of hypotheses and data, a condition that is required to derive Bayes' rule (Edwards, 1972).

It is important to note that probabilistic reasoning is a deductive process. The classical approach to statistics maintains this approach by evaluating the probability of data under a given hypothesis regarding the parameters' value. The Bayesian approach, in placing a probability distribution on parameters and updating it with data, turns the statistical process into an inductive one, violating historical views of the scientific method (Fisher, 1960).

Bayesians historically have had a number of responses to this criticism, ranging from the philosophical to the pragmatic. First, and perhaps foremost, Bayesian statisticians take a completely different view than classical statisticians on the nature of probability, and the difference between the classical and Bayesian view of probability has been, and continues to be, discussed at

the very onset of the introduction of Bayesian thinking in almost any text (Box and Tiao, 1973; Gill, 2002; Lynch, 2007; Robert, 1994). Specifically, Bayesians argue that, although a parameter of a distribution may, in fact, be a fixed quantity, the fact that we do not know its true value justifies placing a probability distribution on it, or otherwise discussing it using the language of probability, and we do so in almost every real-world scenario. For example, when we discuss whether it will rain tomorrow, the fact is that it either will or will not rain, and we will know the 'parameters' of the world in that case 2 days from now. However, this does not prevent us from discussing today whether it will rain tomorrow in probabilistic terms. It is commonly understood, in that context, that the language of probability is used to represent uncertainty about a state of the world, regardless of whether that state can be known exactly in the future. Thus, in science, it is perfectly reasonable, even if we will eventually know a parameter's value with certainty in the future, that we use the language of probability to summarize our current knowledge of it.

Second, it often does not matter whether we treat parameters of distributions as fixed or random quantities. Put another way, the conclusions that we reach regarding a scientific hypothesis are often substantively the same, regardless of whether we take a classical or Bayesian approach. To be sure, whether conclusions are similar may depend on our choice of prior distribution for θ. Indeed, a long-standing criticism of the Bayesian approach has been that, even if one agrees with a subjective view of probability – that probability is a reflection of uncertainty – that subjectivity can carry over into the process of constructing prior distributions and thereby distort any conclusion that data alone may produce. For example, eqn [3] shows that the posterior distribution for a parameter is essentially a weighted average of the prior distribution for the parameter and the data (this is known as Bayesian 'shrinkage'). Yet, many, if not most Bayesian applications have historically used 'noninformative' (also called 'flat,' 'reference,' and 'uniform') priors specifically with the intent of avoiding injecting much if any prior knowledge into a model and thereby overruling the data in the posterior distribution (Gill, 2002; Gelman et al., 1995; Jeffreys, 1961).

Third, in a less defensive and more proactive manner, Bayesians argue that the Bayesian paradigm is superior to the classical paradigm, because it is, in fact, the way science progresses in a coherent fashion. The classical approach does not allow for the formal accumulation of knowledge; instead, the same ('null') hypotheses are tested again and again and knowledge accumulates only via literature reviews in scientific papers. This approach does not formalize the advance of science. In contrast, under the Bayesian approach, the current state of knowledge regarding a scientific hypothesis is contained in the prior distribution, and our knowledge is updated with each successive study. Although a prior study may begin as subjective construct, scientific consensus eventually molds the prior into an objective claim about reality.

Since the 1990s, Bayesian statistics has made considerable headway into mainstream statistics and science, because many statistical and scientific problems are very amenable to the Bayesian approach. For example, in recent decades, computer science has found the Bayesian approach to be very useful in machine learning and artificial intelligence more generally. Similarly, in social science, the large-scale collection of data following a hierarchical structure, either in terms of spatial hierarchies like students nested within schools, communities, states, or repeated measures on individuals collected over time (i.e., panel data), has made Bayesian analysis increasingly popular because of its ability to handle such hierarchical structuring easily. In short, in both 'hard' and 'soft' sciences, the explosion of computing power has enabled the use of Bayesian methods in areas in which it was not possible to use earlier and for which the classical approach was ill suited.

Applications Prior to 1990

Bayesian statistics held a relatively marginal status in statistics and science more generally prior to 1990, but there were numerous applications, nonetheless, many of them outside of the world of statistics itself. In general, the term 'Bayesian statistics' was not used in early applications. Instead, Laplace's term 'inverse probability' was preferred. After Bayes and Laplace, the theorem essentially disappeared – with much criticism – for roughly half a century. Near the turn of the twentieth century, the theorem began to reemerge in practical, applied (but not theoretical) settings. For example, the French army, under Joseph Bertrand used Bayes' theorem to update their artillery positioning (i.e., reaim it), and the mathematician Poincare used Bayes' theorem in a defense of Alfred Dreyfus in the 'Dreyfus affair' (McGrayne, 2011). In the US, Bayes' theorem found use in business, both in communications and the insurance industry. However, Bayes' theorem remained largely out of favor in academia, in part due to long-standing criticism by Fisher and Neyman who had developed their own approach (now called the 'classical' approach) to addressing scientific–statistical hypotheses. To be fair, however, Jeffreys, working at the same time as Fisher, kept Bayesianism alive.

During World War II (WWII), Bayes' theorem emerged in several areas. Turing used Bayesian logic to solve the 'enigma' code, and others used Bayesian logic to help the Allies to locate U Boats, and thereby protect commercial and military ships. Following WWII, Bayesian approaches continued to be used in private industry and expanded into medical research, albeit without the 'Bayesian' label (McGrayne, 2011). Additionally, Bayesian statistics reemerged in academia, with a key book by Savage published in 1954 (Savage, 1972).

The period between the 1950s and the 1980s saw only a slight increase in the use of Bayesian statistics in academia, and the stagnation was due to two key factors. First, *within* the Bayesian 'community' there was a disagreement over the nature of prior distributions. Specifically, some argued for an explicit subjective view of probability and prior distributions, while others argued for more objective, less informative priors like Jeffreys' priors.

Second, because Bayesian analysis requires heavy computation to either approximate integrals or compute them via 'brute force,' limitations of computing power restricted realistic and large-scale Bayesian applications. The evolution of personal computers and the accompanying explosion in computing power in the 1980s enabled more realistic Bayesian applications to be undertaken.

In short, the application of Bayesian thinking and methods, while spanning more than two centuries, has been marked by general disdain with periodic revivals in academia. Outside of academia, the Bayesian approach has found a more steady application, but generally under the guise of 'inverse probability' and not under the 'Bayesian' name (McGrayne, 2011; for a very detailed, nonmathematic history of Bayesian statistics). In the 1990s, the tide turned.

Since 1990

The number of Bayesian applications exploded in the 1990s, and so I limit the discussion here to the key issues that enabled this explosion and the direction of Bayesian research since then. Prior to 1990, solutions to most Bayesian applications were analytically intractable and required either computer-based numerical methods approaches and/or approximations based on normal distributions and normal mixture distributions. These approaches required computational and other skills that are specialized knowledge, especially prior to 1990, and so Bayesian analysis was restricted to those who both appreciated the paradigm and could implement it. Additionally, the use of approximation methods obviated one of the key benefits of Bayesian analysis: the ability to conduct more realistic analyses that did not require simplifying assumptions and appeals to asymptotic normality.

In 1990, Gelfand and Smith published a truly seminal paper introducing sampling methods as an approach useful for constructing summaries of posterior distributions. The logic behind sampling methods is that summaries of samples from a distribution can provide equivalent information as analytic summaries of a distribution. For example, sample quantiles are asymptotically equivalent to what is obtained via integral calculus or numerical integration (Gelfand and Smith, 1990).

The difficulty with simulation methods is that it is difficult to sample from distributions of high dimensional and/or unknown forms. Gelfand and Smith showed, perhaps most important, that high dimensional problems can be broken into lower dimensional, conditional ones, and repeated, sequential sampling from conditional distributions produce samples that, for all intents and purposes, can be treated as samples from the joint, multivariate distribution. These samples can then be summarized using basic descriptive methods, just as one would summarize sample data. This approach is called 'Gibbs sampling' and is one of a number of methods of 'Markov chain Monte Carlo' (MCMC) simulation methods.

A more general sampling approach – the Metropolis–Hastings (MH) algorithm – emerged subsequently as an alternative to Gibbs sampling. To be sure, the MH algorithm predates Gelfand and Smith's paper by more than three decades, but its application prior to the 1990s was limited to the applications in physics. Following the publication of Gelfand and Smith's paper, it was shown that Gibbs sampling is a special case of MH sampling. Together, MH and Gibbs sampling have been used in literally thousands of applications, leading to a tremendous increase in the application of Bayesian statistics.

Importantly, in 1996, an edited volume, entitled *Markov Chain Monte Carlo in Practice*, was published. This volume not only illustrated the use of MCMC methods for a variety of substantive problems, but also presented methodological advances in MCMC computation, including evaluation of model fit and model comparison, foreshadowing subsequent advances in Bayesian statistics. That is, since the mid-1990s, most advances in Bayesian statistics have been in terms of (1) improvement in MCMC design and implementation for various, often idiosyncratic applications, and (2) model evaluation and comparison. Regarding both areas, the free package WinBugs has played a key role in helping to routinize the application of Bayesian statistics (Lunn et al., 2000), enabling the number of scholarly papers adopting a Bayesian approach to explode.

Since the mid-1990s, the number of applications of Bayesian methods is too numerous to detail. From January 1971 to January 1991, a 'Web of Science' search found that there were 2160 papers involving the key word 'Bayesian.' Over the following 20 years, there were 40 242. Thus, publications involving Bayesian statistics – by this cursory measure – increased by a factor of roughly 19. To put this in context, given that the number of scientific journals and publications therein in general increased over that time period, I also obtained counts of articles for several other key words, including 'tornado,' 'beef,' 'fish,' and 'climate.' For 'tornado,' citations increased by a factor of 2. For 'beef' and 'fish,' citations increased by a factor of 3 and 7, respectively. Finally, for 'climate,' citations increased by a factor of 21. In sum, the growth in the key word 'Bayesian' has kept pace almost with the growth in the key word 'climate,' an impressive feat, given that interest in climate change has increased tremendously over the last 20 years.

Conclusion

In conclusion, Bayesian statistics has a long, storied history. For the better part of two centuries, Bayesian statistics was mired in theoretical disputes that rendered its use in academia negligible. However, its practicality was recognized outside of academia in several areas in which updating knowledge systematically was (and is) critically important. In recent decades, expansion in computing capability has led to the widespread adoption of Bayesian methods, and its growth in use shows no deceleration. Indeed, the Bayesian approach may become the dominant paradigm in statistics within another generation.

Abstract

An important underlying determinant of wage discrimination, as well as the gender wage gap, is the way the labor market rewards individual physical attractiveness. This article surveys the extensive empirical literature of the effect of physical attractiveness on labor market outcomes. Particular attention is given to the channels through which attractiveness may affect individual labor market outcomes and the way attractiveness affects gender wage differentials. Further research is needed on the effect of attractiveness within occupations in order to provide more evidence on its productivity-enhancing channel of transmission and the effect this has on the gender wage gap.

Introduction

The labor economics literature has exhibited a long lasting interest in the examination of wage discrimination (*see* Discrimination, Economics of). This article has generated huge amount of research by economists. So far, a large sum of careful empirical studies of wage discrimination based on gender, race, and disabled workers, etc. have been produced. In recent years, discrimination in the labor market against a unique group – those physically unattractive/attractive – has brought increasing attention primarily because the number of employment-related discrimination claims based on employees' appearance has continued to increase (Malos, 2007). In July 2001, the city and county of San Francisco released compliance guidelines to prohibit weight and height discrimination in the local labor market. In 2008, the District of Columbia enacted a series of protection measures for employees, by making it illegal to discriminate on the basis of outward appearance for the purpose of recruitment, hiring, or promotion (Hamermesh, 2011) All these local legislations are aimed at protecting those that could find themselves in the physical appearance disadvantaged group. Although, not everyone in the past agreed that these type of efforts should take place (Barro, 1998).

The first economic study on the relationship between appearance and labor market outcomes, which laid a solid foundation for the studies afterward, was provided by Hamermesh and Biddle (1994). The focal point in this strand of the literature is to determine (1) whether labor market outcomes differentials based on physical appearance exist; and (2) if they exists, what are their potential explanations. Identifying the magnitude of the effect of physical appearance on labor market outcomes (known also as the beauty effect) and the channels through which they work can be critical as policy implications may vary across the various explanations. The effect of appearance may also vary across genders, which, in turn, may affect individual labor market responses (as well as the opportunity in the marriage market), differently. Therefore, studying the beauty effect across genders may help explain the observed gender wage inequality (or gap) to some extent. Further, beauty-based labor market outcome premiums (or penalties) may vary in across cultures and across countries, thus the study of country differences may shed light on the establishment and development of antidiscrimination laws in other countries.

This article reviews the large literature on the impact of physical attractiveness on labor market outcomes. The focus is on beauty and it is not the goal of the survey to provide an exhaustive review of other physical appearance attributes (such as height and weight (*see* Obesity and Labor Market Performance), etc.). Section What Is Beauty? Beauty Measure and Alternative Measures briefly introduces the definition of beauty and the beauty measures. Section Potential Explanations of Beauty Premium/Plainness Penalty summarizes the potential explanations of beauty premium/plainness penalty. Section Empirical Estimation Methods reviews the empirical models used to estimate the effect of beauty. Section Gender Differences discusses the beauty effect across genders. Section Country Findings lists the findings of the beauty effects across countries. Section Conclusion concludes.

What Is Beauty? Beauty Measure and Alternative Measures

Seldom have researchers offered a conceptual definition of physical attractiveness primarily because a physical attractive person is hard to define precisely. In Hatfield and Sprecher (1986) the authors define physical attractiveness as someone "(…) which represents one's conception of the ideal in appearance; (…) which gives the greatest degree of pleasure to the senses." By characterizing most previous research, Morrow (1990) proposes a definition of physical attractiveness from an inductive perspective: physical attractiveness is the degree to which one's facial image elicits favorable reaction from another. Although these two definitions of physical attractiveness are fairly consistent, there are few consistent standards of attractiveness across cultures (Hatfield and Sprecher, 1986; Hamermesh and Biddle, 1994) Fortunately, it has been shown from previous studies that, within a culture at a point in time, there is tremendous agreement on beauty standards and these standards change fairly slowly over time (Hamermesh and

Biddle, 1994) These conclusions made from a psychological and sociological view indicate that attractiveness is at least potentially measurable.

In psychological research, the most common way in which the concept of attractiveness is measured is by asking raters to judge the physical attractiveness of people in portrait photographs or to use self-reported appearance ratings. According to the theory mentioned above, physical attractiveness measured in this manner should have high reliability because people within a given culture tend to agree with each other regarding whether a person's facial appearance is attractive or not (Hatfield and Sprecher, 1986; Umberson and Hughes, 1987; Hamermesh and Biddle, 1994). (Although Doorley and Sierminska (2014) find that interview measured attractiveness can exhibit a 'personality'effect and vary from beginning to the end of the interview.) In addition to the attractiveness measures induced from evaluating photographs, others have used alternative measures emphasizing other aspects of physical attractiveness. These alternative attractiveness measures include height/stature (Frieze et al., 1991; Loh, 1993; Steckel, 1995; Persico et al., 2004; Deaton and Arora, 2009; Loureiro et al., 2012), weight/obesity/BMI (*see* Obesity and Labor Market Performance) (Larkin and Pines, 1979; Haskins and Ransford, 1999; Register and Williams, 1990; Frieze et al., 1991; Loh, 1993; Averett and Korenman, 1996; Maranto and Stenoien, 2000; Cawley, 2004; Loureiro et al., 2012; Caliendo and Gehrsitz, 2014), appropriateness of dress (Lambert, 1972), hair color (Johnston, 2010), and physical disability (Loureiro et al., 2012). Among all these alternative measures, height and weight are commonly used in economics literature. Some researchers point out that these two measures are less subject to measurement error, do not depend on subjective ratings from observers, and also play a fundamental role in the perception of attractiveness. However from a point of view of validity (or construct validity) these two measures are still not sufficient as the physical attractiveness of a person is more than standard height and weight.

Potential Explanations of Beauty Premium/Plainness Penalty

A large body of literature has documented that above-average looking workers receive a wage premium while below-average looking ones receive a wage penalty. The quandary, then, is why does there exist beauty premium/plainness penalty and through which channel can physical attractiveness affect earnings? Possible explanations for the channels cited in the literature include employer discrimination; customer discrimination/productivity; occupational sorting; and attractiveness affecting individuals' cognitive/noncognitive skills that are important for job performance. While the empirical evidence in support of some of these explanations is relatively thin, the attention they receive in the literature leads us to discuss each of these in turn.

Employer Discrimination

There are two conceptually distinct reasons employers might wish to hire more attractive workers. The first is based on a belief that good-looking workers are more productive or more capable even when workers ability is not observed. The second is that employers simple prefer to work with good-looking workers even when they do not have a biased belief about the workers actual ability. The former reason is attributed to an employers' biased belief or stereotype, while the later is Becker type discrimination (*see* Discrimination, Economics of).

People respond differently to attractive and unattractive individuals in a work setting. In general, people tend to be favorably biased toward those who are more attractive (Hatfield and Sprecher, 1986). One may wonder why these attractiveness effects occur. Research by Miller (1988), Dion et al. (1972), and Snyder (1984) provides the most straightforward answer from a psychological point of view. In their studies, they show that one's impression/belief based on the observation of someone's physical attractiveness affects the way one responds to that person. This type of belief assumes that physically attractive people have more socially pleasing personalities and that they are more likely to be successful in their careers. This biased belief can be particularly important when employers are making hiring decisions during face-to-face interviews. In fact, earlier psychological studies have confirmed the stereotype hypothesis, which predicts that attractive people are more likely to be hired for a variety of jobs (Dipboye et al., 1977; Riggio and Throckmorton, 1988). (Hamermesh (2012) finds that decision-makers are still more likely to respond to absolute rather than relative differences among physically attractive people.) The 'taste-based discrimination,' on the other hand, is developed by Becker (1971). In his book, he introduces the first economic model of discrimination. Becker's model assumes that employers have disamenity value to employing minority workers. In the beauty context, minority workers represent the unattractive workers. Employers may have unbiased beliefs about workers' performance but prefer hiring comparatively attractive people. Therefore, unattractive workers may have to accept a lower wage for identical productivity or, equivalently, be more productive given identical wage. Hamermesh and Biddle (1994) and Harper (2000) both provide strong support for employer discrimination against unattractive or short workers.

Although the effect of attractiveness on earnings is shown to be attributed to employer discrimination, it is still difficult to determine whether employer discrimination is due to biased belief or distaste. The reason for this is that household survey data usually do not provide information regarding workers' job performance realization, employers' estimate of a worker's ability, and employers' reaction in wage adjustment if workers' true performance is observed. Fortunately, this difficulty can be overcome under experimental settings in which worker and employer's wage negotiation process can be observed as well as workers' task-solving skill that is unrelated to physical attractiveness. Examples of laboratory experiments used to examine the beauty effect channels include Mobius and Rosenblat (2006) and Deryugina and Shurchkov (2013a). Both studies have found that employers' biased belief on the ability of attractive workers (through visual and oral stereotype) explains a large proportion of the beauty premium. Specifically, the latter one points out that the beauty premium can only be obtained from specific tasks (e.g., bargaining instead of data analysis or data entry). In the experiment, the authors

repeat the wage bidding for several rounds and find that when the workers' true ability is revealed, the beauty premium completely vanishes due to the employers' quick learning process.

Customer Discrimination/Productivity

It is possible that physically attractive workers are more productive than unattractive ones in some occupations, such as actors/actress, sales assistant, and waiters/waitress, etc. (*see* Erotic Capital). These types of occupations typically involve extensive interaction between workers and the customers. Therefore, such an advantage could arise from customer discrimination with customers preferring to interact with better-looking workers. Moreover, physical attractiveness may enhance workers' ability to engage in productive interaction with coworkers. Good working relationship with coworkers and the firm's clients can create a form of firm-specific human capital, which generates higher earnings for workers themselves and higher quasi-rents for their employers (Pfann et al., 2000).

It is been shown that attractive salesmen generally enjoy the benefit from customer discrimination. Reingen and Kernan (1993) suggest that buyers in the attractive-salesman condition are significantly more likely to grant a demonstration appointment and buy the product in a simulated buying–selling setting. Moreover, perceptions of attractiveness appear to induce buyers to behave more favorably toward attractive sellers. Using actual salespeople's data in shopping malls, Sachsida et al. (2003) results point out that women with good appearance receive a reward of approximately 9% in their earnings and this reward is entirely induced by the productivity effect and not discrimination. Hamermesh and Biddle (1994) and Biddle and Hamermesh (1998) also examine whether productivity accounts for the beauty premium using household survey data and a sample of law school graduate data. However, their results only provide weak support for productivity-related discrimination. Hamermesh and Parker (2005) continue to test this hypothesis using a sample of university instructors. Although they are able to uncover a positive association between standardized beauty scores and students' class ratings, they are still not able to disentangle the effect that stems from productivity difference from the one that stems from discrimination. Using an advertising industry sample, Pfann et al. (2000) show that executive's beauty raises firm's revenue, and the increase in firm's revenue far exceeds the extra wages that good-looking executives obtained. Therefore, executives' beauty enhances firm's human capital and the wage premium obtained is primarily induced by productivity. In sum, the evidence provided from above suggests that productivity-related discrimination is highly occupational specific.

Occupational Sorting

It is reasonable to believe that one's physical attractiveness can help to determine the occupational choice that one makes as a worker. As it is been mentioned above the effect of attractiveness could be fairly large in occupations, which involve extensive interaction with customers (like sales assistants). However, one's occupational choice is not only based on the advantages that one believes he/she has, but also on one's preferences regarding different activities and one's ability to perform different types of work. To put it differently, an individual does not choose to enter occupations solely based on one's appearance and the potential payoff to one's appearance in various occupations. The occupation decision also depends on individual characteristics other than appearance such as education level, past work experience, marital status, and parents' occupations, etc. That is why attractive workers are observed in greater proportion in occupations in which attractiveness is rewarded, but not all individuals who work in occupations where beauty pays are attractive (and we find attractive people in occupations where beauty does not pay off). The fact that people see less variation in looks within an occupation than in the workforce as a whole is attributed to the fact that segregation in appearance is incomplete. On average, better-looking individuals choose occupations where looks are important, and below-average looking individuals avoid these types of occupations.

The occupational sorting channel has been investigated by several studies. Hamermesh and Biddle (1994), Biddle and Hamermesh (1998), Harper (2000), and Doorley and Sierminska (2012) all have found empirical support for the standard implication that workers who are well endowed with beauty choose the type of occupations where the payoff to appearance is high. Liu (2014) shows that more attractive women are more likely to participate in managerial/administrative jobs while less likely to choose operative/craftsmen jobs. In particular, Biddle and Hamermesh (1998) extend the traditional sorting model to account for dynamic sorting of beauty using a longitudinal survey data. Using a sample of law school graduates, they first split the sample into individuals who work in private sector and public sectors 5 and 15 years after graduation. They then investigate the sector-switching pattern based on attractiveness. Their results show that lawyers who left the private sector between year 5 and year 15 are less attractive than those who stayed (controlling for other characteristics), while lawyers who switched from the public sector to private sector are more attractive than those who stayed. Their results provide evidence of dynamic sorting in directions consistent with changes in the relative returns to the individual characteristics.

Beauty Correlated with Cognitive/Noncognitive Skills

Another explanation for the existence of the beauty premium is that beauty may in fact be positively correlated with certain cognitive/noncognitive skills such as test score, communication skill, confidence, leadership skills, personality, etc., which are rewarded in the labor market or enable workers to enhance labor productivity (Feingold, 1992). These cognitive/noncognitive skills are usually acquired during adolescent period through socialization or activities in high school. It is been shown that attractiveness at a younger age may contribute human capital investment during adolescence because good-looking children are given more attention by teachers and peer (Lerner et al., 1990; Langlois et al., 2000). An extensive body of research indicates the importance of cognitive/noncognitive skills obtained during high school in future labor

market outcomes, such as test scores, college enrollment, social behavior, employment, occupational attainment, and wages (French et al., 2009; Cobb-Clark and Tan, 2011; Carneiro et al., 2007; Heckman and Rubinstein, 2001; Heckman et al., 2006; Jacob, 2002; Kuhn and Weinberger, 2005). Persico et al. (2004) investigate the wage premium resulting from being tall. They point out that the height premium actually comes from teenage height instead of adult height. Being tall during adolescent period increases the likelihood of participation in high school sports and clubs. Participation in these activities promotes the acquisition of confidence, which in turn increases future wages. Mobius and Rosenblat (2006) and Scholz and Sicinski (2014) reach similar conclusion using attractiveness measures. They find that more attractive individuals exude better communication skills, more confidence, and more extroversion, which all translate into higher wages. Mocan and Tekin (2010) evaluate the attractiveness effect on criminal activities and finds that unattractiveness increases a young adult's propensity for criminal activity. They argue that this is primary due to the fact that unattractiveness hinders student human capital development during high school. Han et al. (2011) examine the direct and indirect effect of teenage body weight on adult wages and find that education is the main pathway for the indirect BMI wage penalty. They find that the BMI wage penalty is underestimated by about 18% for women and is not statistically significant for men.

Individual's cognitive skill such as test score and study performance may also be correlated with attractiveness. Von Bose (2012) and Deryugina and Shurchkov (2013a) both show that physical attractiveness is positively correlated with high school Grade Point Average (GPA) and university overall GPA. Others have shown that beauty and ability are complements at high levels of beauty, but substitutes at low levels (Fletcher, 2009).

Empirical Estimation Methods

The primary method used in the literature to model the beauty effect on labor market outcomes is a Mincer type human capital model or wage equation. This type of model regresses individual earnings (or log hourly wage) on categories of attractiveness (e.g., above-average and below-average), a set of productivity-enhancing characteristics (e.g., years of schooling and potential experience, etc.), and a vector of individual characteristics (e.g., race, marital status, union status, self-reported health status, etc.). As it has been mentioned above, attractiveness may also be correlated with cognitive/noncognitive skills. If these determinants are not controlled for, the estimated effect of attractiveness could be biased. Therefore, previous studies sometimes include IQ scores, high school activities, and if the data allow the 'big five' personality traits (openness, conscientiousness, extraversion, agreeableness, neuroticism). The coefficients on the attractiveness measure represent the marginal variation in wage in relation to beauty. Almost all the previous literature (including the psychological, sociology, and economic literature) have adopted this type of linear model to construct baseline beauty effect estimates (*see* Wage Differential and Structure).

A less commonly used approach is introduced by Doorley and Sierminska (2012), who use distribution regression followed by an Oaxaca–Blinder style decomposition (Oaxaca, 1973; Blinder, 1973). The primary reason to adopt this methodology is that the authors posit the effect of beauty may vary across the wage distribution. To proceed, they start by estimating the conditional distribution of wages in different attractiveness group (e.g., beautiful and plain) given individual characteristics. They then construct counterfactual wage distributions. The final wage differentials between beautiful and plain workers can be decomposed into the characteristics effect and the unexplained difference. The unexplained wage differentials are interpreted as the beauty premium/plainness penalty.

One limitation of the Mincer type model and the distribution regression is that these methods do not allow for the potential channels to be separately identified. The empirical model proposed by Hamermesh and Biddle (1994) solves the problem to some extent. They propose the following regression:

$$w_i = \beta_0 + \beta_1 X_i + \beta_2 \theta_i + \beta_3 \mathrm{OCC}_i + \beta_4 \theta_i \mathrm{OCC}_i + \varepsilon_i$$

where w_i represents log hourly earnings. $\mathbf{X}_i$ is a vector of productivity-enhancing characteristics. θ_i is a binary variable that equals to 1 if the worker is attractive and 0 otherwise. $\mathrm{OCC}_i = 1$ if the worker's occupation is as one where looks are productive. The ε_i are residuals. This regression nests a model of occupational sorting, employer discrimination as well as a productivity differential. The occupational sorting model implies $\beta_3 > 0$. The productivity/customer discrimination model implies $\beta_4 > 0$ and $\beta_2 = \beta_3 = 0$. The employer discrimination model implies $\beta_2 > 0$ and $\beta_3 = \beta_4 = 0$. Examples of studies using the Hamermesh and Biddle (1994) model to examine the beauty effect channels include Harper (2000), Sachsida et al. (2003), Loureiro et al. (2012), Doorley and Sierminska (2012), and Johnston (2010), etc.

Although the above model provides a convenient method to test the existence of potential transmission channels of the beauty effect, it is not without its caveat. One difficulty with using this model is to determine the set of occupations where looks are likely to enhance productivity. Clearly, there is no simple rule of thumb. In Hamermesh and Biddle (1994), the authors use three different sources to identify these occupations. These sources include the *Dictionary of Occupation Titles* (1977), three-point scale ratings on whether appearance might be important to a specific occupation by eight raters, and a survey conducted by Holzer (1993). According to their classification, the occupations in which attractiveness could possibly enhance productivity include sales occupations, cashiers, receptionists, and waitresses, etc. These occupations evidently involve more interaction between workers and customers. Doorley and Sierminska (2012) divide occupations into dressy and nondressy taking advantage of a survey question asking individuals' opinion on the importance of appearance in their professional life. In their dressy category, within which beauty may enhance workers' productivity, they identify occupations such as supervisors/managers, intellectual professions, administrative employees, service, and sales employees, etc. The occupations included in their dressy category are shown to be generally consistent with the original 1994 Hamermesh and Biddle paper.

Another difficulty in using this model is to disentangle the productivity channel from other sources. Although Hamermesh and Biddle (1994) are able to provide some support for productivity-related discrimination, the evidence is fairly weak. A related explanation, they provide, is that there are still inherent productivity differences that the data do not capture because of omitted variables. Due to this reason, alternative variations need to be incorporated to better identify this channel. One approach is to use data from workers who are from a relatively homogeneous group (a specific occupation). Biddle and Hamermesh (1998) intend to overcome this difficulty by using a sample of graduates of a particular law school. To measure the wage differentials from consumer discrimination or productivity, they compare earnings between attorneys practicing in the private sector and those in the public sectors. The reasoning behind this research design is that, in the private sector, the duties of lawyers often include a marketing component in that they have to attract new clients and keep the existing ones. In public sectors, however, the ability to market one's services is not an essential part of the job. Therefore, the earning difference between private and public sectors also reveals customers' discrimination. In order to further separate the effect stemming from customers preferring to spend time with better-looking attorneys and away from the effect stemming from customers' belief that better-looking attorneys are more productive (obtain greater financial gains), the authors examine how mean attorneys attractiveness differ by legal specialization within the private sector. This test helps to determine whether attorneys' attractiveness can assist them in generating more favorable judgments from clients in each legal specialty. The results from these comparisons, however, only provide weak evidence for the belief that beauty produces more advantageous outcomes.

Even with the ability to estimate the impact of physical attractiveness on individual earnings, the literature still leaves open the question of how to separately identify productivity-related discrimination. Due to the fact that measures of productivity are fairly few and they are aggregated, given the heterogeneity of respondents' occupations in publicly available household survey, data on relatively homogeneous workers in specific occupation is definitely called for. The literature studying customer discrimination within occupation is still relatively thin, making this a valuable area for future research.

Gender Differences

The effect of attractiveness on labor market outcomes may vary with respect to gender. This is primarily due to the fact that attractiveness may result in different labor market opportunities for men and women. Although the participation gap has been narrowing, in general, women are still more likely than men to stay out of the labor force (additional information can be found in Family and Work; Earnings Inequality; Income Inequality.). This observation is particularly common for the 1970s when women's stated goal was 'career then family' (Goldin, 2004). During the 1970s, about 65% of married women were in the labor force at age 30 (Goldin, 2004), while overall about 97% of men were employed while only 57% of women were in the labor force (Liu, 2014). What determines women's labor force participation decision apart from marital status, number of children and education? Beauty endowment may be one of these factors. As discussed in Section Potential Explanations of Beauty Premium/Plainness Penalty, it is possible that more attractive women will be able to gain more from a job than a less attractive counterpart. More attractive women may be more likely to work because beauty brings them more confidence (Mocan and Tekin, 2010) and they may be more likely to take advantage of their attractiveness if it enhances their productivity at work. On the other hand, the disincentives associated with bad looks may lead women to avoid the labor market (Hamermesh, 2011). Hamermesh and Biddle (1994) investigate this point and show that married women with below-average looks are 3–11% less likely to participate in the labor market than above-average looking women. Harper (2000) finds that the probability of unemployment falls from 2 to 0.9% for attractive women. Borland and Leigh (2014) suggest a relatively large negative effect (about 18 percentage points) of below-average beauty on women's probability of employment. Women's self-selection into the labor force based on beauty endowments alters the distribution of observed female beauty in the labor market. Since more attractive women are more likely to appear in the labor market and vice versa, one observes less female beauty variation and, therefore, a smaller beauty premium. However, selection based on beauty endowment is less prevalent for men given men's fairly high labor force participation rate, thus, one expects to observe larger beauty premium for men than for women.

Although women's self-selection explains the beauty premium gender differences, this explanation is only appropriate when women's labor force participation rate is low. From the 1970s to 2000s, married women's labor force participation continued to expand (Goldin, 2006) and a narrowing of the participation gap between men and women has occurred (Goldin, 2014). In 2012, the labor force participation rate for men between 15 and 54 years of age was about 89%, which is only 14% higher than that of their female counterpart (BLS, 2013). Due to the converging roles of men and women in the labor market and at home over the past 40 years, the observed female beauty variation in the labor market should be largely expanded. Therefore, the beauty premium gap across genders is expected to decrease.

In the end, gender differences in the beauty premium/penalty is an empirical issue. Careful studies on gender difference in the effects of attractiveness on earnings show that the above hypothesis is general true. By stacking two American and one Canadian data set, Hamermesh and Biddle (1994) report that men who are assessed as being homely are penalized about 9% in hourly earnings while those who are viewed as having above-average looks receive an earning premium of 5%. Among women, there is a 4% attractiveness premium and a 5% plainness penalty in hourly earnings. Harper (2000) shows that men who are rated as unattractive at both ages 7 and 11 incur a large and significant pay penalty of 14.9%. This pattern also applies to their female counterpart with a 10.9% unattractiveness penalty. One point that needs to be noticed is that Harper (2000) attractiveness measures are obtained from evaluating adolescents' appearances by their teachers. Since adolescents' appearance may change dramatically when people get older and

may also contain relatively large measurement error, it is possible that the estimates suffer from attenuation bias. Borland and Leigh (2014) show that, in the 1980s, above-average beauty for men is associated with a premium of 11.6% and below-average beauty with a penalty of 10.4% with the latter effect being statistically insignificant. For women, however, no statistically significant attractiveness premium or unattractiveness penalty is found. They conclude that over time (1984 and 2009) the returns to beauty from the effect on a worker's hourly wage are more or less constant. Mocan and Tekin (2010) also confirm a similar pattern using a sample of young adults. Their results suggest that, using all three survey waves, the beauty premium is 4.5% for women, and being unattractive is associated with a 7% reduction in wages. The wage premium to be very attractive for men is 10.8%, and the penalty for being unattractive is the same amount as women (7%).

The above hypothesis regarding gender differences still holds even within specific occupations. Frieze et al. (1991) investigate the attractiveness premium using a sample of 737 MBA graduates between 1973 and 1982. They first conduct a Chow Test to confirm that the salary relationships for men and women are different. They then estimate the beauty effect separately by gender. They find that more attractive men obtained higher starting salaries and continued to earn more over time. For women, however, there exists no effect of attractiveness on starting salaries although more attractive women begin to earn more with greater job experience. Biddle and Hamermesh (1998) examine the payoff of law school graduates who graduated in the 1970s and 1980s. Their results indicate that the attractiveness effect of men is statistically significant 5 years after graduation with two standard deviation increases in attractiveness score associated with about a 10% increase in earnings. The estimated attractiveness effects for women, however, are indistinguishable from zero. Clearly, the measure of labor market outcomes may not be limited to individual earnings. Any measure that evaluates the performance in an occupation can be used as an outcome variable. In the case of university teaching, course/instructor evaluations are reasonable measures of teaching performance. A number of studies have shown that better teaching evaluations increase teachers' salaries (Moore et al., 1998; Kaun, 1983). Therefore, teachers' attractiveness may have an indirect impact on their salary via students' class ratings. Hamermesh and Parker (2005) evaluate beauty in the classroom. They find that a one standard deviation increase in the attractiveness score is associated with a 0.38-point increase in male teachers' class ratings while the beauty effect for female teachers is less than half compared to that of males.

Although the (women's) self-selection hypothesis is generally supported by previous studies, it is not uncommon to see studies that reach different conclusions. French (2002) is one such example. In this article, the sample data used is collected from two worksites (a nonprofit hospital and a large school district) in a Midwestern community in 1995–97. Using self-reported appearance as a beauty measure, the author finds that women with above-average appearance obtain about 8% higher earnings relative to women with an average appearance. There is no evidence that shows that women suffer from the plainness penalty. For men, neither the beauty premium nor the plainness penalty is detected in the regression results. Liu (2014) finds that gender differences in the beauty effect vary with the individual's age. The results suggest that men in their mid-1930s have no significant beauty premium. For women, on the other hand, a one standard deviation increase in the attractiveness rating is associated with a 5.4% increase in the hourly wage. At a later stage of the career (early-1950s), men's attractiveness premium develops with one standard deviation increase in attractiveness score associated with 2.65% increase in hourly wage while women's attractiveness premium fades. However, their findings are consistent with the narrowing beauty premium gap hypothesis mentioned above.

The gender wage gap literature has indicated several sources of wage inequality across genders. These sources include workers' observed characteristics, gender-specific workforce composition change (Mulligan and Rubinstein, 2008; Ruffle and Shtudiner, 2010), collective bargaining effect (Blau and Kahn, 2003; Sachsida et al., 2003; Antonczyk et al., 2010; Scholz and Sicinski, 2014), competition (Weichselbaumer and Winter-Ebmer, 2007), and work-time flexibility (Goldin, 2014). However, these studies do not consider the potential effect of physical attractiveness on individual earnings across genders. The literature reviewed in this section above confirms that gender differences in the beauty premium do exist and indicates that the role attractiveness plays in explaining the gender wage gap could be bigger than previously assumed.

Country Findings

It might be futile to search for a universal standard of beauty since they are determined within cultures (Hatfield and Rapson, 2000) and the variation of cultures around the world results in few consistent standards of beauty (Hatfield and Sprecher, 1986). One question one may want to ask is whether people in different culture all favor beauty? Is the beauty premium/plainness penalty consistent across different countries? In order to answer this question, we compare findings from previous international studies. The comparisons are shown in **Table 1**.

Evidently, physical attractiveness is rewarded in almost all country findings, except for men in Luxembourg. Among all the countries listed, the beauty premium in Germany and China are the highest (from 17.9 to 20%), especially for women. The largest plainness penalty shows up in studies investigating British and Australian data (from −10.9 to −14.9%). Interestingly, Harper (2000) and Borland and Leigh (2014) estimates show that individuals in the United Kingdom and women in Australia do not receive any attractiveness premium. This similarity in the payoff of attractiveness may be due to the similarity in the historical economic structure, as well as culture in both countries. The reader should notice that **Table 1** presents selected country findings from the literature. Some studies that investigate the beauty premium have adopted either an alternative attractiveness measures (e.g., height, weight, hair color, etc.) or used alternative labor market outcomes (e.g., whether individual gets called back during hiring process). Ruffle and Shtudiner (2010) and López Bóo et al. (2013) are examples of this kind of research. Both papers examine the link between beauty and hiring practices but use sample from different countries. Ruffle and Shtudiner (2010) investigate

data from Israel while López Bóo et al. (2013)look at data from Buenos Aires, Argentina. Both studies provide evidence that attractive people receive more responses (callbacks) from employers than unattractive people. Also, the attractive ones tend to receive callbacks sooner than their unattractive counterparts. (An interesting discussion on the possible way to reduce unfair advantages related to physical appearance can be found in Krause et al., 2012.)

Conclusion

The attention given to beauty-based discrimination has increased in recent years. As this article has shown, most previous studies in this area focus on estimating the magnitude of the effect of physical attractiveness on labor market outcomes and trying to identify channels through which attractiveness can affect these outcomes using various survey data sources. This body of literature generally confirms the existence of a positive association between physical attractiveness and various labor market outcomes such as individual earnings and employment opportunity (callback rate). Moreover, several explanations (e.g., employer discrimination, customer discrimination/productivity, occupational sorting, etc.) of how beauty affects labor market outcomes are provided.

As it is mentioned above, all explanations are supported by previous studies to some extent; the empirical evidence in support of some of the potential explanations is still relative thin. This is particularly true for the productivity channel. Therefore, researchers could contribute in this area by using within occupation specific data, where workers can be viewed as relatively homogeneous. Additionally, this would partly remove the unobserved factors of productivity.

Another area where researchers could help shed light is the endogeneity of beauty. In previous studies, physical attractiveness is generally treated as exogenously determined. However, perceived attractiveness may be correlated with clothing/cosmetics spending, plastic surgery, and parents' attractiveness; these are usually not observed from survey data. Failing to consider the endogeneity issue may cause the estimated beauty effect to be biased upward.

Abstract

As the author of *The Second Sex* (1949), a radical and multidisciplinary essay on women, Beauvoir has come to be considered as a seminal feminist theorist. In her essay she deconstructs the cultural myths that construct femininity, examines the way in which women have historically been positioned as the other or object to men as subject, and analyses the weight of social and material oppression to which women have been subjected. Combined with this socially-constructionist analysis of the workings of patriarchy, Beauvoir nevertheless retains a belief in the possibility of individual agency and a freely chosen identity that sets her apart from more recent postmodern accounts of gender.

Novelist, philosopher, essayist, and autobiographer, the author of one of the founding texts of feminism in the twentieth century, Simone de Beauvoir can be considered to be one of the major intellectual figures of her generation. Born in Paris on 9 January 1908 into a conservative middle-class milieu, she received the narrow primary and secondary education deemed appropriate for a marriageable girl of her class. However, after a sudden deterioration in her family's financial circumstances, she was permitted to study philosophy at the Sorbonne, and in 1929 she became the youngest person ever to succeed in the prestigious *agrégation de philosophie* examination, a success which enabled her to earn her own living from a series of teaching posts which she held first in Marseilles, then in Rouen and, from 1936, in Paris. Occupying a series of cheap hotel rooms, she led a remarkably independent life, free from domestic obligations, and, despatching her teaching in the minimum time necessary, she spent her days writing in cafes and participating in a complex web of relationships, at the center of which was the couple she formed with Jean-Paul Sartre. The two never set up home together, setting their face against the idea of marriage and children, but referred to their close circle of former pupils and ex-lovers as 'the family.' The outbreak of the Second World War disrupted both this network of relationships and Beauvoir's assumption that her freedom was virtually total. As she writes in her autobiography she had to 'face the weight of reality.' Continuing her life in occupied Paris without Sartre she completed the manuscript of her first novel, *She Came to Stay* (1943), an exploration of the Hegelian dictum 'Each consciousness pursues the death of the other,' and went on to publish in quick succession *The Blood of Others* (1945), exploring some of the ethical and political dilemmas posed by the Resistance, and *All Men Are Mortal* (1946) which deals with the problem of the historical dimension of human existence. Sartre, meanwhile, had completed his philosophical essay *Being and Nothingness*, also published in 1943; in postliberation Paris the couple became famous figures as existentialism, as Sartre's philosophy came to be known, dominated the Parisian intellectual scene. In 1946 Beauvoir turned her attention to the situation of women, and in 1949 published the two volumes of radical and multidisciplinary thinking which constitute *The Second Sex*. Its frank treatment of sexuality and its critique of the maternal role expected of women made her a figure of some notoriety, and though she went on to write bestselling novels, and won the Goncourt prize for *The Mandarins* in 1954, her name was forever to be associated with her seminal work of feminist theory. From 1958 onward she also began to publish volumes of autobiography, constructing an account of life as a twentieth-century intellectual woman followed by millions of readers worldwide. The 1950s also opened up a phase of active political engagement as she campaigned against French atrocities in Algeria during the Algerian war, supported the Maoist groups in the events of 1968, and, in the 1970s, joined with the newly formed MLF (Women's liberation movement) in campaigns on abortion, contraception, sexism, and violence against women. After Sartre's death in 1980, she published his letters to her, and her own letters both to Sartre and to her American lover Nelson Algren, were published in 1990 and 1997, respectively, after her own death in 1986. It is thus as philosopher, feminist, activist, novelist, memorialist, and correspondent that Beauvoir has made a deep mark on her era.

Nonetheless, it is principally as the author of *The Second Sex* that Beauvoir has come to be considered as one of the most significant feminist voices of the twentieth century. Beauvoir's study of women began life as an autobiographical question (what had it meant to her personally to be a woman), developed into an essay about the cultural myths which construct femininity and eventually became an ambitious multidisciplinary work, studying women's situation from a panoply of directions to demonstrate that 'one is not born, but rather becomes, a woman.' This crucial distinction between sex and gender was to open up the entire field of women's and gender studies. Beauvoir stresses in the introduction that her approach is ontological and existentialist: if there is no fixed human nature then neither can there be a fixed nature for women. This intellectual origin does indeed provide a strong impetus to the work, driven by the assumption that, like all human beings, women can and should shape their own destinies. However, the existentialist approach stresses individual responsibility rather than the way in which patriarchy functions as an institution and, taken to the extreme, it could suggest that women's oppression is a form of individual bad faith.

One of the strengths of *The Second Sex* is that although Beauvoir does not admit explicitly the extent to which social

and economic analyses complement her ontology, she does in fact offer a balance between the weight of social, cultural, and economic oppression on the one hand, and the free construction of the subject on the other. Her argument that women historically have been positioned as the object or 'other' to men as subject is supported by a socially constructionist view of patriarchy.

The book begins with a series of attacks on the notion that there is a fixed destiny for women. In part 1 she investigates what biology, psychoanalysis, and Marxism appear to prescribe about female destiny to conclude that women are not defined or inevitably doomed to oppression by the laws of nature, by their psychoanalytic situation, or by economic history. The section on psychoanalysis attacks Freud for his definition of female sexuality in terms of penis envy, an attack that was responsible for a long feminist mistrust of Freud. The section on biology as destiny has proved particularly controversial since, despite insisting that female physiology offers no justification for the hierarchy of the sexes, Beauvoir paints a dispiriting picture of the daily experience of the body for women. In her account the female body is organized to such a high degree to ensure the reproduction of the species that it constitutes a burden against which women must continually struggle in their bid for freedom. Part 2 is devoted to a wide-ranging survey of women's historical role from Ancient Greece and Rome up to the 1940s. It describes women as fundamentally handicapped by maternity from the earliest times, stresses women's role as a medium of exchange, and analyses how tools of patriarchy such as Christianity and the feudal system have corralled the vast majority of women into the margins of historical narratives. Moving on to the myths of femininity, in part 3, Beauvoir dissects a rich set of constructs ranging from the Christian images of Mary and Eve to the pervasive myth of feminine mystery. The section ends on a discussion of five male writers, showing how literature has served as a vehicle for the creation and circulation of myths about women. This analysis later became the inspiration for the work of Kate Millett and the branch of feminist literary criticism that reads male-authored texts with a deconstructive eye.

Parts 4 and 5 of the essay turn to the social and sexual roles which women are called upon to play, tracing the way in which the girl gradually becomes socialized into her role as wife and mother, under the eye of her own mother, the unwitting accomplice of patriarchy. Up to the age of puberty Beauvoir nevertheless credits the young girl with a strong sense of her own autonomy; it is at the moment when the traits of female sexuality install themselves in her body that the girl sees the social trap closing, according to Beauvoir. A section considering female sexual response and case histories of women's first experiences of sexuality follows. Drawing on the Kinsey Report, and on other studies of sexuality, Beauvoir gives serious and detailed consideration to female sexual pleasure, including a discussion of the supposed distinction between the vaginal and clitoral orgasm. She also devotes a chapter to lesbianism in which she rejects the idea that lesbianism is an anatomical or physiological destiny. On the contrary, she presents it as positive choice for women that can lead to an authentic exercise in freedom just as much as heterosexuality. Unsurprisingly, she does not produce a theory of lesbian identity, since she consistently presents identity as following from choice and acts, not as preceding action and being.

Part 5 examines the two central roles which patriarchy calls upon women to play: those of the wife and the mother. Romantic love is in itself a dangerous condition for women, Beauvoir argues, because it tends to encourage their dependency on men and discourage them from pursuing their own goals. Marriage she describes as based on an obscene principle, because it makes a duty of what should be a freely given exchange. Her attack on the role of wife is closely linked to the role of women as maintainor of the home – the thankless round of domestic tasks that have by their nature to be repeated endlessly without achieving any final aim are described graphically by Beauvoir, and the illusory joys of the gleaming interior are analyzed with penetrating insights. Motherhood, another concomitant of marriage, is presented as even more problematic. Pregnancy acts as a positive incitement to women to sink passively into a fixed destiny; after the birth, the mother–child relationship is described as a battlefield yielding few positive results for either party. She concludes that the upbringing of children care is unsafe within maternal hands and should be organized within a collective framework. Beauvoir's analyses of the dangers and social pressures of the roles of wife and mother bring sharply into focus her dual insistence on, on the one hand, the weight of social conditioning to which women are exposed, and, simultaneously, individual women's responsibility to resist such pressures. Women are both victims and complicitous.

The final two parts of the book are entitled 'Justifications' and 'Towards liberation.' In part 6, 'Justifications,' Beauvoir considers some of the false routes which women have taken in a doomed attempt to flee from their responsibility by glorying in their imprisonment. One route is that of narcissism, in which the woman cultivates her body in an impossible attempt to be simultaneously subject and object, simultaneously both source of the gaze and object of it. A second false route is that of mysticism, the attempt to achieve sovereign being through an identification with God – also, for Beauvoir, an impossibility. The third route is that of the *amoureuse*, the woman who makes a cult of her love for a man whom she has appointed as her savior. She aspires to authenticity by attempting to live vicariously through him. Beauvoir demonstrates both the philosophical impossibility of this stance and the inevitable destruction that it brings about of the relationship on which the *amoureuse* depends, as she becomes increasingly tyrannical.

Part 7, entitled 'Towards Liberation,' offers a synthesis of women's situation and a portrait of 'The Independent Woman.' Beauvoir shows how women's blocked situation even creates what we think of as the female character. The reader is urged to accept that femininity is a social product – if we can accept this, she argues, then we can change society to change the possibilities open to women. She insists on the importance of economic independence for women, and pleads for men and women to work together toward a better future, but she has no confidence that anything of substance can be achieved without a radical restructuring of society. The independent woman is

not in a position to achieve much without the socialist revolution that Beauvoir assumes, in 1949, would create a society in which everyone would be free. This rather unsatisfactory ending is indicative of the exploratory, theoretical rather than campaigning spirit in which Beauvoir wrote the book; it was not until over 20 years later, in the context of French second wave feminism, that Beauvoir declared the necessity of actively pursuing the women's struggle independently of any broader political movement.

On its publication in French in 1949 the book caused moral outrage; the Catholic novelist Francois Mauriac, led a newspaper campaign to have it banned as pornography, and it was in fact put on the Index. Its status as a daringly sexy book written by a woman seems to have partly obscured its political thrust, and the French postwar climate was particularly inimical to the language of women's rights. In America the book was translated in a truncated form by the zoologist Parshley, and it was this version, published in 1953 and still the only English language version available today, which a generation of American and English women including Kate Millet, Betty Friedan, Germaine Greer, and Anne Oakley read during the 1950s and 1960s. Through them the work began to exert its influence, although they did not always acknowledge their debt. Betty Friedan, for example, whose book *The Feminine Mystique* (1963), is often considered to have been the launch pad for the American women's movement, offered her readers a watered down version of Beauvoir's analysis of the housewife and has only one mention of her in the index, which refers to the charge by an American critic that Beauvoir 'didn't know what life was all about' and 'besides she was talking about French women.' Where Beauvoir offers a radical critique, insisting that the institution of the family must be destroyed, that women must become economically independent, and that a radical restructuring of society will need to take place, Friedan advises women to think about their personal growth. However, it is atleast arguable that in translating some of Beauvoir's analyses into terms acceptable to a more conservative audience, Friedan did act as a channel of communication between two cultures in which political radicalism historically have played very different roles.

The key phrase 'one is not born, but rather becomes, a woman' is, as Haraway (1991) writes, at the root of 'all the modern feminist meanings of gender' and has been developed in many different directions. Butler (1986), for example, in a reading of the phrase, stresses Beauvoir's use of the verb 'becomes,' arguing that it allows for a process of gender acquisition that is a daily act, an interplay between individual choice and acculturation of which 'styles of the flesh' are a constitutive part. This important article prepares the way for some of the influential theoretical texts which Butler has gone on to write in the 1990s: *Gender Trouble* (1990) and *Bodies That Matter* (1993) propose a performative theory of gender which build on and develop Beauvoir's original insight. Second-wave feminism in France had a complicated relationship with Beauvoir. The construction of 'French feminism' in the Anglo-Saxon world as being constituted uniquely by the theorists of difference, Cixous, Irigaray, and Kristeva, whose theories are at odds with Beauvoir's stress on individual agency and freedom, has tended to obscure the work of other French feminists such as Christine Delphy and Monique Wittig working in Beauvoir's radical tradition. Feminists reading *The Second Sex* 50 years after its first publication encounter a number of problems: the text's ethnocentricity, its tendency to regard masculinity as unproblematic, the distaste displayed for the female body, and the devaluation of the maternal are largely at odds with contemporary sensibility. Despite this, there is considerable evidence in the 1990s of a renewed interest in *The Second Sex*, as the feminism of difference finds itself in turn in difficulties. Thus, Moi (1994) writes: 'In an intellectual field dominated by identity politics, *The Second Sex* represents a real challenge to established dogmas: if we are to escape from current political and theoretical dead ends, feminism in the 1990s cannot afford to ignore Beauvoir's pioneering insights.'

The Second Sex, with its confidence in the possibility of individual agency and a freely chosen identity, combined with an awareness of how patriarchal structures are at work in the construction of female subjectivity, offers a third way through the choice between essentialism on the one hand and postmodern dissolution of the subject on the other. *The Second Sex* founded many of the feminist strands of scholarship that are being pursued – in women's history, in philosophy, in literary criticism, in social studies. It offers a model of the multidisciplinary approach that the study of women requires, and has made the discussion and theorization of gender possible. It was not intended originally as a manual of liberation or a political tool, but it became one through the impact it had on others. In her autobiography, Beauvoir describes her own astonishment at discovering, in her forties, that there was a way of looking at women with new eyes; that vision is one which has now become a part of our consciousness.

Abstract

German sociologist Ulrich Beck (Ludwig Maximilian University in Munich, London School of Economics and Political Science) is best known for his work on risk, globalization, and reflexive modernization. His groundbreaking book *Risk Society* (1992) sparked international interest, debates, and scholarship on the topic of risk. His most recent work has promoted moving beyond 'methodological nationalism' by developing an innovative social science made for a cosmopolitan twenty-first century.

Ulrich Beck is a German sociologist best known for his pioneering work on the concept of risk within the context of globalization and reflexive modernization. Beck's most influential work *Risk Society* (1992) presents a theoretical conceptualization of 'risk' as an organizing force in what he terms the 'risk society,' which has emerged as the values and institutions of early industrialization become increasingly self-critical at the same time when modern technologies unleashed potentially catastrophic, unintended consequences. In his subsequent work, the idea of a global 'risk society' is situated within a framework of 'reflexive modernization' wherein the social structures and institutions of the twentieth century come to be characterized by increasing complexity and uncertainty rather than fulfilling modernity's promise of scientific certainty about the natural and social world. This perspective argues that the structural and institutional configurations of early modernity (e.g., gendered division of labor, social class, nation-states) are becoming increasingly detached from individual experiences, giving rise to a plurality of idiosyncratic individual-level options for organizing social relations and managing risks. At the same time, the 'hazards' created by the forces of modernization such as pollution, climate change, and nuclear and biological technology are becoming increasingly global and not bounded by national borders or existing social categories. As such, these global risks in this second modernity cannot be adequately addressed by the institutions of nation-states as they are currently constituted. Beck's work has long highlighted these social changes and the crisis of reflexive modernization, proposing epistemological and political solutions for understanding and managing emerging global risks by advocating a more cosmopolitan vision for addressing the consequences of a global risk society.

Biographical Information

Ulrich Beck was born in 1944 in Stolp, Pomerania and grew up in Hanover, Germany. Beck earned his PhD in Sociology from Ludwig Maximilian University in Munich in 1974, and was awarded Habilitation in 1979. After working as professor of sociology at the University of Münster from 1979 to 1981, and at the University of Bamberg from 1981 to 1992, Beck worked as professor of sociology at Ludwig Maximilian University in Munich until 2009 when he became professor emeritus. He has also held the British Journal of Sociology Visiting Centennial Professorship at the London School of Economics and Political Science since 1997. Since 2008 he has been a Fellow at the Centre for Advanced Studies of the Ludwig Maximilian University in Munich, and since 2009 he has held the Senior Loeb Fellowship of Harvard University, and is a senior research fellow at Max Planck Institute, Gottingen, for the study of religious and ethnic diversity. In 2011, he became one of 15 internationally distinguished inaugural chairs in the College of Global Studies at Fondation Maison des Sciences de l'Homme, Paris. His work has earned him honorary doctorates from Sofia University St Kliment Ohridski and Varna Free University in Bulgaria, the University of Buenos Aires in Argentina, the University of Lausanne in Switzerland, the University of Eichstätt-Ingolstadt in Germany, the University of Madrid in Spain, the University of Macerata in Italy, and the University of Jyväskylä in Finland.

He has received numerous prestigious national and international awards including recognition by the German Sociological Association in 2004 for contributions to public sociology, the prestigious Schader Prize from the Schader Foundation in 2005, and a German–British Forum Award (along with Anthony Giddens) in 1999 for contributing to international dialogue between the two nations. His books have been translated into more than 35 languages, and his work has been cited and expanded upon by scholars in as many nations. At the time of writing this article, *Risk Society* has been cited over 20 000 times according to Google Scholar. The small selection of 69 of his journal articles that are indexed in Web of Science have been cited over 1600 times, including 248 citations in 2012 alone (the most recent full year indexed). From 1999 to 2009, he was the founding director of the Reflexive Modernization Research Center (SFB 536) funded by the German Research Foundation to develop interdisciplinary, collaborative research projects to empirically investigate the forces and consequences of social change. The scientific conversations started by Beck's pioneering works on risk have contributed to international scholarly discourse in a wide range of social science fields including sociology,

psychology, criminology, economics, management, and political science.

Most recently, Ulrich Beck was awarded an Advanced Investigator Grant by the European Research Council entitled "Methodological Cosmopolitanism: In the Laboratory of Climate Change," which pioneers research to address methodologies for advancing social sciences beyond the boundaries of 'methodological nationalism.' In this work, Beck is working to develop concepts and analytic techniques which are used to study global environmental risks that are more cosmopolitan and less dependent upon nation-states as the unit of analysis.

Major Works

Risk Society

The English language publication of Ulrich Beck's *Risk Society: Towards a New Modernity* (1992) directly contributed to a proliferation of research into the social and political consequences of risk narratives in the context of rapid social and technological change. In *Risk Society*, Beck argues that forces of rationalization and industrialization gave rise to what he terms 'early modern' (later called 'first modernity') social institutions, but rapid technological change quickly outpaced society's ability to control and check the unintended consequences, or risks, of these technologies. Late or 'second modernity' is characterized by a situation in advanced societies in which most of the basic material needs of citizens can been met, and yet in the process new hazards have been "unleashed to an extent that was previously unknown" (Beck, 1992: p. 19) by the very technologies that gave rise to this level of material comfort.

For Beck, risk is "defined as a systematic way of dealing with hazards and insecurities induced and introduced by modernization itself" (Beck, 1992: p. 21). He theorizes that in contrast to genuinely external hazards (e.g., natural disasters), risks are reflexive, politically driven narratives about the *potential* for hazards to arise from modern institutions or technologies. Further, he argues that the potential hazards of late modern technologies are (1) global in their potential consequences (e.g., nuclear disasters or pollution), (2) difficult to perceive without relying on the expertise of the very institutions that created the hazard (e.g., chemists must test for chemical pollutants), and (3) arise not from a lack of resources as with previous hazards (e.g., famine) but rather from an abundance of unwanted consequences arising from modern technologies (e.g., cancer due to exposure to air pollution).

Using examples primarily based in environmental sociology, *Risk Society* succinctly presents the beginnings of an empirical critique of the prevailing concepts of modernity, discusses the epistemological and political consequences of a truly reflexive social science, and situates the concept of risk and the 'risk society' as an emerging consequence and organizing force emerging from radically reflexive modernization processes in the industrial West.

Reflexive Modernization

Beck's critique of modernity, in many ways, paralleled and complemented the work of renowned British sociologist, Anthony Giddens. In 1994 Ulrich Beck, Anthony Giddens, and Scott Lash published *Reflexive Modernization: Politics, Tradition and Aesthetics in the Modern Social Order* and wed their theoretical critiques of rationalization, modernization processes, and the role of social science into a unified and influential theoretical work.

Reflexive Modernization argues that the driving principles behind modernization arising out of the Enlightenment (e.g., rationalization, science) which helped legitimate and give rise to the institutions of industrial and early modern societies have turned these same critical powers in upon themselves. The modernization process, they argue, was so successful that these well-developed critical technologies, in particular social science, began to shift their critique from deconstructing premodern institutions (e.g., religion, cultural tradition) to reflexively deconstructing the institutions to which they had themselves given rise (e.g., sexual division of labor, social class).

The political and social consequences of this reflexivity have resulted in a fundamental shift in late modernity to a world that is increasingly organized around government's ability to manage individuals' perceptions of risk, in contrast to the early industrial society organized around conflicts over access to material goods. In his contribution to this volume, Beck argues that a microlevel consequence of the risk society is the 'individualization' of risk, such that each person becomes radically disembedded and forced to develop idiosyncratic biographies based on an abundance of conflicting options. One of Beck's major points in this work is that political institutions within a self-reflexive society begin to cannibalize themselves, undermining the ability of individuals to trust institutions that are constantly being destroyed and reinvented by modernization processes. Empirically, *Reflexive Modernization* engages these political processes by examining the externalities of technology such as ecological hazards, highlighting the confluence of political, technological, and social technologies around potentially catastrophic environmental risks.

The Brave New World of Work

Beck's extensions of the ideas in *Risk Society* (1992) to the areas of work and political economy have also been influential; contributing to academic debates over precarious work and globalization. In *The Brave New World of Work* (2000a), Beck details the consequences of a transition away from class-based social relations to a social order organized around a risk society. He locates the historical class-based conflict between capital and labor within the boundaries of nation-states, recognizing that multinational corporations are operating increasingly independently from the restrictions of organized labor, or becoming 'deinstitutionalized.' The central thesis in *The Brave New World of Work* (2000a) is that a world risk society is responsible for giving rise to a proliferation of precarious work, where full-time employment is being replaced by contingent and flexible working biographies that are pieced together by individuals in constant states of transition and self-reinvention. Beck calls for the creation of a cosmopolitan civil society of 'world citizens' to organize work and human activity around transnational interest groups rather than nationality.

Other Works

Following the introduction of the key concepts in *Risk Society* (1992) and *Reflexive Modernization* (1994), Beck's work has continued to build upon, develop, and empirically investigate these ideas. In one sense, *Ecological Politics in an Age of Risk* (1995) and *World Risk Society* (1999) more completely develop the political, environmental, and sociological ideas while building an empirical case for the risk society. Other work has attempted to broaden the theory to explain individual and household-level consequences and evidence for the emergence of a risk society, for example, microlevel investigations of risk society concepts from the perspectives of work, family, and intimate relationship among multinational Europeans are taken up in *The Normal Chaos of Love* (1995), *Individualization: Institutionalized Individualism and its Social and Political Consequences* (2002), and *Distant Love* (2014), all coauthored by Elisabeth Beck-Gernsheim. *Individualization* (2002), in particular, expounds theoretically upon the shift from institutional to individual responsibility for managing risk in one's own life, explicitly linking some of the risk society's key tenets with other sociological work on identity politics.

Though not as widely influential as *Risk Society* (1992), *Individualization* (2002) outlines the microlevel and cultural consequences of reflexive modernity. Individualization as described here is a process where individual identity becomes radically decoupled from traditional social structures like work, family, geography, or even social class. This concept is made particularly clear through examples like gender and work, where trade-offs for women force them to choose between traditional institutions of work and family by examining the political and social risks of an increasingly abundant array of viable biographical choices. The connection of a theory emerging social conditions (e.g., the risk society) to empirically verifiable transformations in gender, work, and family configurations is the primary sociological contributions of this work.

The Reinvention of Politics: Rethinking Modernity in the Global Social Order (1997), *World Risk Society* (1999), *Power in a Global Age: A New Global Political Economy* (2005), and *World at Risk* (2009) all to a greater or lesser extent take up the practical and political tension of a global risk society through timely, empirical critiques of how nation-states have responded (often inadequately) to the risks and consequences emerging risk narratives around issues including: nuclear energy, political management of natural disasters, bovine-strain encephalitis (or 'mad cow disease'), terrorism, biotechnology, climate change, financial crises, and numerous other contemporary risk discourses. All of these works theoretically ground these contemporary crises and examples in terms of risk society, reflexive modernity, and the need for cosmopolitan political solutions. For instance, in *Power in a Global Age* (2005), Beck calls for a 'self-critical cosmopolitanism,' arguing that cross-national organizations, political parties, and multilateral institutions are necessary to address global economic, environmental, and security issues. *World at Risk* (2009) effectively and concisely draws together the core of Beck's earlier ideas in a concise and focused diagnoses of contemporary social issues, cutting through nationalist political debates about terrorism, climate change, and the global financial crisis.

Finally, in another major line of work, Beck explicitly explores the sociological and political consequences of Europe's continued reliance on early modern institutions, describing the prevalence and dangers of an enterprise based on a 'methodological nationalism' that takes as unproblematic the historical distinctions between countries, especially in Europe. *Power in a Global Age* (2005), *The Cosmopolitan Vision* (2006), *Cosmopolitan Europe* with Edgar Grande (2007), and most recently *Twenty Observations on a World in Turmoil* (2012) are Beck's efforts to build a practical cosmopolitan sociology. *The Cosmopolitan Vision* (2006) most clearly begins to distinguish between 'first modernity' and 'second modernity,' including the notion that many individuals are passive or coerced participants in the dialectical transition to a 'cosmopolitanized' world. Some of Beck's most influential and well-cited journal articles emerge from this area of research, where he repeatedly challenges sociology to rethink core analytic concepts and categories like class, power, and the 'global flows' of information, money, and popular culture from a new cosmopolitan imagination (Beck, 2000b, 2002; Beck and Sznaider, 2006).

Impact of Work

The global impact of Ulrich Beck's ideas is evident in the expansive proliferation of his work into more than 35 languages. A Google Scholar search for the term 'risk society' returns over 49 000 results; this concept alone has been applied to the study of topics ranging from terrorism to influenza outbreaks, or from electronic surveillance to the study of intimate partner violence. It is difficult to summarize the scope and breadth of Beck's influence in social science, in part, because of his high visibility as a public sociologist in Germany and Great Britain; for instance, he has written a number of editorials for *Die Zeit* in Germany and *The Guardian* in the UK. He has also been praised for his efforts to promote his cosmopolitan vision for sociology through international, interdisciplinary, and intergenerational collaborations (Calhoun, 2010). Ulrich Beck is perhaps the most famous contemporary sociologist in Europe, where his ideas have struck a chord within both the social sciences and the general public.

In the more than 20 years since the publication of *Risk Society* (1992), there has been a prolific expansion of work across disciplines and across continents exploring the conceptualization and consequences of risk in advanced contemporary societies. Beck's *Risk Society* was the first major work in sociology to theorize about risk in a systematic and empirical manner, reinventing and extending Max Weber's concept of modernization in a manner reminiscent of other major contemporary theorists like Jurgen Habermas. Some have gone so far as to credit Beck with pioneering a 'risk turn' similar to the 'cultural turn' of the 1970s and 1980s in social science (e.g., Mythen and Walklate, 2006); Beck himself calls instead for a 'cosmopolitan turn' that reinvents the orientation of social sciences for a globalized world (Beck and Grande, 2010). In this effort, Beck seems to have been successful; both inspiring and leading an effort to overcome 'methodological nationalism' in the social sciences (Chernilo, 2006).

Critics of the risk society perspective have largely focused their criticisms on Beck's definition of risk. Anthropologists and some cultural sociologists cite the work of Mary Douglas (Douglas, 1992; Douglas and Wildavsky, 1982), for instance, in arguing that risk is by no means a new social phenomenon. Instead, the cultural construction of risk narratives has long been a mechanism for boundary maintenance and social control within human societies. Along similar lines, other sociologists draw on Foucaultian theories of power and governance to critique Beck's assertion that second modernity is not only dominated by risks, but that this occurs because late modernity is actually more hazardous due to the inability of society to control the unintended consequences of technology. Dean (1999), for instance, argues that risk is simply "a way of representing events so they might be made governable in particular ways" (p. 131). They argue that the failures of neoliberal policies in European nation-states to respond to problems that transcend national boundaries do not necessarily represent an evolutionary failure of modernity, especially when one attempts to apply this perspective to other parts of the world (Calhoun, 2010). These critics problematize the proposed transition to second modernity that hinges upon the inability of first modernity's social institutions to be able to handle emerging risks.

The comprehensive nature of Beck's theory of a risk society, combined with Beck's tendency to incorporate contemporary political examples into his work has helped his work reach a wide audience within the social sciences. Most directly, Beck's work has helped to frame environmental sociology within the politics of globalization. Cross-national debates over hazards such as nuclear technology, chemical pollutants, and biotechnology easily lend themselves to analysis within the risk society framework, and indeed many of Beck's early works and later examples draw upon this scholarship. However, the ideas of the risk society have implications for the study of work and economy, marriage and family, youth, popular culture, labor relations, criminology, psychology, media, sexuality, and health policy to name a few (e.g., see Mythen and Walklate, 2006).

Beyond the risk society, Beck's most influential contribution to the social sciences has been his extensive work toward envisioning a cosmopolitan global social science. Though theorists had taken up the issue of 'methodological nationalism' previously, Beck is widely credited with renewing this now-vibrant debate within the social sciences (Chernilo, 2006). In *Cosmopolitan Vision* (2006) Beck explicitly distinguishes a 'social scientific cosmopolitanism' from cultural and political cosmopolitanism, calling for the reinvention of analytic categories developed for a global world. This effort builds upon the critique of what Beck has elsewhere called "zombie categories" (Beck, 2002: p. 27), referring to analytic categories rooted in the social conditions of early modernity (e.g., social class, religion, ethnicity, nuclear families) that have ceased to function yet remain the predominant analytic paradigms. Beck's ideas are visionary in the sense that they persistently seek to transcend academic and disciplinary boundaries in a radical way. If the critique of first modernity is that modern institutions (including social science) are organized around outdated social conditions, Beck's vision for sociologists in second modernity is that they will become active and intentional contributors to political discourse, particularly with regard to the framing and management of risks. The explicit recognition that in a reflexive society, the findings and perspectives of science are already being marshaled by political forces to create or direct public concern is Beck's clarion call to sociologists and other experts that social science must be more proactive in addressing and framing emerging global issues if we are to move beyond a risk society.

Beck has been criticized variously as a pessimist in his diagnosis of modernization (e.g., Braun, 1996; Rose, 2000) by focusing only on the risks to the exclusion of the benefits of modern technological advances, or as exceedingly optimistic about the promise and rise of alternative institutions within second modernity (e.g., Kalleberg, 2013). Some have pointed out that Beck's analysis tends to focus on intangible risks in areas such as work and employment (e.g., job insecurity, unemployment) to the exclusion of more serious immediate dangers like workplace injuries (Tombs and Whyte, 2006). Others have identified limits to Beck's work on developing cosmopolitan political alternatives to state-based strategies, noting that many individuals still only experiences global risks as mitigated through the actions and decisions of the state (Donoghue, 2011). These types of critiques in the context of a global recession and growing economic inequality also raise serious doubts about the extent to which advanced societies have actually developed beyond the point of conflicts over wealth, social class, and material security.

The importance of Ulrich Beck's scholarship within sociology and social science is undeniable. Regardless of his critical reception in specific fields, his works have nevertheless prodded social scientists across disciplines and around the world to consider the consequences of globalization, risk, and reflexive modernization within their own work. The debates led by Beck and his many collaborators and colleagues have helped to dramatically advance a renewed interest in social theory developed for the twenty-first century.

Abstract

Howard S. Becker's intellectual career can be summarized under five headings. The first addresses his background and intellectual influences. The second, his introduction of 'perspectives' as a tool to understand the medical academic world and public school teacher's relation to social status and career. His best-known work *Outsiders* relates to drug use, the process of becoming an outsider and the labeling theory, this is his third center of interest. His fourth interest is reflected in *Arts Worlds* published in 1982, which compares the professional artistic world to the mavericks and outsiders. Finally, some of the tricks of the sociological trade and cases end this article.

Intellectual Influences

Howard S. Becker was born on the 18 April 1928 (Chicago, Illinois), he was a scholar in what is now called the second Chicago school, although several sociologists (e.g., Jennifer Platt) deny that interpretation of the Chicago department of social sciences after World War II (Platt, 1995). In many interviews H.S. Becker alludes to the influence and friendship with Everett Hughes and to the influence of G.H. Mead's writings in his analysis of the self in the interaction process. He had been a student in criminology with E.W. Burgess. Like Saul Alinsky he does not really acknowledge the courses on criminal behavior, nevertheless he wrote an introduction to the *The Jack Roller: A Delinquent Boy's Own Story*. In criminology he more often mentions Donald R. Cressey and Edwin H. Sutherland and their work on white-collar crime. The anthropologist Lloyd Warner is quoted in his biographical interviews. At the time H.S. Becker was a student at Chicago, Warner was directing the extensive *Yankee City Studies*. This important piece of urban work gave many a student an opportunity to go in the field with other graduate students and led them to reflect on methodology and empirical work. He and Erving Goffman belonged to the same circle of students and quite often he relies on Goffman's image of society as a stage on which actions take place. Becker's MA thesis (achieved in 1949) was first published in a series of articles and then, in 1963, as the well-known book *Outsiders*. His PhD in the Willard Waller tradition (1951) was about Chicago teacher–student relations, it gave rise to many articles gathered in a book published by the London Open University Press in 1995 entitled *Howard Becker: On Education*.

In his interviews Becker often refers to Everett C. Hughes' influence. We could say that both Hughes and Becker had, while in the field, '*a sociological eye*' and often grasped the microdetails, which gave way to an understanding of the whole social setting. While going into a classroom most observers see only the backs of the pupils, the lesson going on, and the day-to-day school routine, but Becker would find out the tricks of the trade and while interviewing teachers he learns about questions of social status, race problems, and much more. Like Robert E. Park and E.C. Hughes who invented and made use of '*their own concepts*': bastard institutions, perspectives, student careers, and the back stage of institutions, so did Howard Becker when he began his master's thesis *Outsiders*. While in Germany in 1948, Everett Hughes mentions in his diary that he was a little awkward about it, he calls them *our funny American concepts* and was wondering if they would seem appropriate to German students (Guth, 2010) , and so it was. Howard S. Becker following E. Hughes' example and with the anthropologist Lloyd Warner learned from the field, furthermore one might say that he was the one who carried off the definition of the situation (W.I. Thomas) in its different aspects either in Medical School or in the collective use of marihuana. One influence, which is often underestimated, is that of William Foote Whyte (Whyte, 1943) who was giving courses to the Chicago students in the late 40s, and had among his students Howard S. Becker and Eliot Freidson. Whyte's pragmatic approach to the field, the people he met and describes, his attempt to theoretical description with set events, and his interaction frame analysis were seen as a good example of what a student could learn from the field. Whyte's approach became, for Howard Becker, a sociological perspective, an ideal of what the field experience is able to stand for. Thus the second Chicago school can be seen as a reflexive school, especially on methodology, grounded theory, and group interaction processes. We should not forget that at the time Becker graduated, the most important book was Moreno's sociometric studies (Moreno, 1953).

In the following we are going at first to see what Becker's study of medical students and medical institutions brought to sociological theories and then referring either to his PhD (Becker, 1951) on the one hand or to the collective and remarkable study *Boys in White* on the other hand (Becker et al., 1995a), we will show how teaching, careers, and students' perspectives illustrate the interaction process. Criminology and deviant behavior will follow with *Outsiders* (Becker, 1963) and his introduction to *The Jack Roller* (Shaw, 1966). Finally, we will end with his lifelong interest in art worlds, music, jazz photographs, and, the questions about field studies, will conclude this article.

Students' Perspectives, Teaching, and Social Status

Students' Perspectives

One of the key concepts in *Boys in White* relates to the *perspectives* that are seen as a collective and comprehensive

meaning of one's future as a physician in Medical School. The perspectives are observed through the learning process: personal time, turning points in (their) apperception of their future, and the final motivations at the end of the learning process in Medical School.

The student's choice of the medical profession is at first an idealistic one and it remains such all along and can still be seen at the end of the process, but it becomes more realistic and less holistic. The Freshmen students want to save lives and cure patients from disease, this is in their opinion the very purpose of the physician. The first problem they encounter in their studies is the huge amount of work and knowledge asked for, and the short time left to apprehend it all. For most of them it seems to be an almost impossible task, so they have to secure a scheme of learning, which will lead to a successful grade. Since the amount of knowledge that is asked for is so huge and time left is so short, they try to reduce the items using different indicators. What is more important and what is less? There are several answers to that question, first they may ask a sophomore and see what the former Freshmen students have been doing, this can be seen as an answer to the issue, an other way of answering that question is the comparison with the manual looked at as a normative reference, and a third way of answering the question is to try to guess what the professors want and what is more important. In these three ways of solving the problem they establish a comprehensive hierarchy of knowledge which they assign to two categories: what is making the grade, and what will be useless. Of course with these indigenous categories they closely examine the former exams and add statistical data to their handling of the cognitive hierarchy. This shows the gap between the idealistic and long-term perspectives and the short-term issues with which the students have to deal. The authors call them the *initial perspectives*. As the studies advance the perspectives, which belong to a collective interpretation of the process of social action, change. Students recognize that they cannot learn all that is asked for, they become realistic especially after a *shotgun* and a block examination (p. 108), it was a focus for students discussions, most of them arrived at the following conclusion (p. 111):

1. In spite of all our efforts we cannot learn everything in the time available.
2. We will work just as hard as ever, but now we will study in only the most effective and economical ways, and learn only the things that are important.
3. Some students said: We will decide whether something is important according to whether it is important in medical practice.
4. Other Students said: We will decide whether something is important according to whether it is what the faculty wants us to know.

This is the provisional perspective, the last perspective led them to the idea that their knowledge about medical practice could not be a help in deciding what was most needed and what was not, they finally came to the conclusion that they had to study what the faculty wanted them to know. They study a little less and spend 60 study hours a week, instead of the original 77 (p. 169), they think that they are more efficient in their work compared with the first months of the freshman year.

Teaching and Social Status

Howard S. Becker's PhD unpublished dissertation (1951) *Role and Career of the Chicago Public School Teacher* gave rise to a number of articles which were republished in 1995 by Robert G. Burgess: *Howard Becker on Education*. Becker's past work fits very well with the new sociology of education in Great Britain and, along with Woods, Hammersley, Hargreaves, Colin Lacey, etc., it gives a new impetus and an ethnographic view to the field. When H.S. Becker was working in the field Lloyd Warner was still publishing his Yankee City series. Becker made use of Warner's status scale and was sensitive as was W.F. Whyte, to the middle-class norms and values developed in the settlement house, finding similar references in school culture. The variations in pupil–teacher relations are observed through three adjustments: teaching, discipline, and moral acceptability. He distinguishes in the different classes a lower–lower stratum, a middle-class stratum, and an upper-middle-class stratum. He looks first at performance which is quite different for middle-class students and lower class students; the latter have another scale of prestige and reward in the slum areas in which they live. In these areas children do not have good working habits, they do not seem interested in learning. Therefore, the teachers in such neighborhoods know that some of the kids are just waiting to quit school; in primary school, teachers cannot do what is expected. For example, at K (a good school) they are able to have nine words a week in spelling although in D (slum school) they are only able to achieve six words. Children have poor reading ability in the poor neighborhood and the teacher has to deal with a lack of ability, that is why the level of expectation is not very high and teachers are satisfied if the children can read and do simple sums (p. 35). Discipline is difficult in the slum schools, there is always a latent tension and one has to be on the edge in order to prevent violence and aggression. In lower class status groups physical aggression is part of a daily behavior among males, it is a behavior approved of and sometimes encouraged in those areas. That is why teachers have to be able to deal with such hardships while teaching. Teaching in middle-class areas where pupils are docile and eager to learn can be a real pleasure, it is not the same with lower–lower classes nor with upper–upper classes. The children of higher status classes can be hard to handle they are seen as spoiled and overindulged, they do not take orders at home and would not take them at school; that is why some teachers begin their class year being tough the first day, but they have to be consistent over the year.

The third item of moral acceptability refers to the group status. The upper class kids have more often learned politeness and respect for their elders while the others lack cleanliness, hygiene, and moral habits; some girls are prostitutes on the side. Above all, the lower class students do not approve of education, they do not want to learn and cannot see the use of being in school, in that sense the moral values of the teachers (individual striving, success, and social mobility) are denied.

One of Becker's best papers in 1952 relates to public school teacher's careers. What happens in the long range? Which turning points in their career might be found? Do public school teachers become principals when they grow older? Do they go

from school to school, from low-status school to higher status schools? Becker calls those changes, adjustments in a career, in a hierarchy of ranked positions, but most of the Chicago career movements are horizontal, at least during a certain period, the teacher keeps teaching maybe for as much as 20 years. Among the teachers examined, the main movement was between the various schools in the Chicago district. Under the Chicago Board of Education Rules teachers had to stay a whole year in order to apply for a transfer, they could apply to as many as 10 positions. If an opening occurred the principal had to approve of the applicant. The young teachers began their careers in the less desirable schools and then moved to more desirable schools, mostly in better surroundings. The teacher's movement was a movement from the least valued surroundings to a better neighborhood or nearer to one's home. But the nicer schools may not have been what they seemed, an authoritarian principal and the school might be worse than the one the teacher had just left, some are just *faux amis*. The principal's choice could be a personal choice, if he did not want the new applicant, he let them know saying that the new teacher would not be happy and this might be a self-fulfilling prophecy. So it seems one had to learn what is hidden behind a vacancy, via an understanding of the neighborhood, the personality of the principal, the social status of the students. All those elements had to be given some consideration in order to make a move. After the first move, many thought they would stay a while in the neighborhood before making a decisive move nearer to home.

Howard S. Becker draws attention to the different changes that take place in the first or second school in which the teacher works. At first the teacher may get adjusted to this low-class environment, his skills and his comprehension of the situation are developing, he becomes acquainted with his colleagues, some might even become friends, he is developing his social system within a social system. His expectations, his perspectives become more realistic that explains why a small number of teachers spend their whole career in only one school. The changes that occur in a teacher's career are linked to their expectations, a young teacher wants to teach an enormous piece of knowledge but he will not be able to do this, a little later he understands that he will never be able to teach such a vast amount of cultural items, he lowers his level of expectations in order to meet the childrens' abilities. While such adjustments are operating, the teacher belongs more and more to a professional network and to the neighborhood network, it becomes more and more easy to have relations with the children's parents, as time passes the teacher becomes known in the neighborhood. In American cities such as Chicago, neighborhoods are changing, with new inhabitants, the movement of more recent immigrants into the transitional area. One of the teachers interviewed says: *The neighborhood used to be ninety 95% Jewish. Now I do not think there are over 40%Jews. The rest are Greek, Italian a few Irish, it's pretty mixed now. And the children are not that nice as they used to be.* So staying a long time in the same school may not be the best policy, in the example quoted, the school changed, its pupils were no longer the same and their parents had perhaps more problems understanding English and the way of life of an American School. The problem might be much more serious in the slum district where discipline is difficult to maintain. If discipline was kept under control by a principal with authority, if he retired or if he went to another place, the whole school might change: a lack of discipline may induce a high turnover. The new principal may want to have his own way and, on the one hand, small privileges based on common understanding between teachers might disappear when the principal leaves. On the other hand, it can be a new opportunity for young teachers who felt that they were on the periphery of the school, with a new principal they strive to be at the center of the institution. Becker wondered why so few were willing to take the exam for principal and found that the answer lies in the horizontal mobility. A teacher goes from a poor neighborhood to a better one, each change is a success in the mobility process, but if he succeeds in his principal's exams, he has to go back to were he came from: *at some low class colored school (Those schools are nearly always vacant, so you have a very good chance of being assigned there when you starts in)*. There is an upward mobility, but at the same time one may go back where one has started, that explains why many do not try to take the principal's exams.

Labeling Theory, Drugs, and Addiction

The epigraph of '*Outsiders*' quotes William Faulkner's I: *It ain't so much what a fellow does, but it's the way the majority of folks is looking at him when he does it* this is the major argument of the book. In a sense it is quite a Simmelian point of view with reciprocal interactions, what W.F. Whyte called: a set event. "I am labeled in the eyes of others," it is an interaction between the group and the individual seen as a law breaker. When H.S. Becker was writing his MA it was still the golden age of group studies. Deviance is, among others, a labeling process – one is deviant when one is seen such although there are social factors which put blame on one and not the other. An unmarried mother is a deviant, which it is not the case of the father; the African American is more often seen as an offender compared to the white American. Some of the rules belong to a single social group, if a Jew breaks the rules of the kashrut it has no effects on the rest of the society; some offenses are limited to a community and Robert E. Park saw deviant behavior as limited to a specific urban area.

The labeling process is a sequence of social action with steps leading to deviant behavior:

1. Marihuana is in use in the given social situation.
2. A personality variable is now at stake, the given person will use marihuana with the other members of the group, he might be even unaware of the lawlessness of his behavior.
3. Even if the first experiences might not be so positive, he goes on using it. The group is showing him how to use the dope and how to get it.
4. He is now a member of a deviant group in which he learns to carry on the deviant activity with the less difficulty. He has now performed the deviant career, most of the deviant careers are alike such as thieves (E. Sutherland) they need a social milieu in which deviance take place.
5. The last process is rationalizing. Up to that moment the drug user is engaged only with people having the same habits or having the same behavior. The marihuana user neutralizes conventional attitudes, and shows that his behavior and his addiction are perfectly normal and manageable; one finds out that he is able to work even while

being high. Drug use is no longer a form of deviance, it is a way of enjoyment and is even much cheaper than alcohol. The marihuana user is almost sure that there is no addiction, it differs in that sense from opium and so he believes that he may stop at any time.

In the Festschrift in honor of Everett C. Hughes *Institutions and the Person: 2010*, Becker compares the user of marihuana to the user of lysergic acid dithylamide (LSD). Becker wants to demonstrate that the LSD psychosis issue might be a wrong interpretation of the drug symptoms. Getting high, too high is for the newcomer in drugs associated with going crazy and might be followed by a reaction of panic. Becker compares the group of marihuana users in which the effects of drugs are socialized and explained to the new user, so he understands what is happening to him and what to do to prevent becoming *too high*. The single user of LSD who is not surrounded by a group of users, and without any drug culture, might be frightened by the effects of the drug and have a panic reaction, often associated, as Becker suggests, to psychosis. Such an interpretation through his historical review of articles was given to marihuana: he has listed interpretations of marihuana use from 1920 to 1940 when it was at first introduced, up to 1940 when it has spread, the psychosis explanation was commonly used, and then, when drug use became more common, it disappeared. Will this be the fate of the comprehension of the effects of LSD? At that time, unlike oriental drugs such as marihuana and opium, which have led to a drug culture and a set of surroundings for drug use, and groups of users, the acid users might be increasing, but they show a different relation to the drug. In both studies *Outsiders* and the comparison of marihuana users to LSD users, Becker insists on the relation to the group of users compared with the individual user. The former involves a socializing process and shares with the newcomer a positive identity and a process of group rationalization while the latter is left alone. Once adopted, the identity changes especially with friends, parents, and colleagues, norms are now at stake: the marihuana user becomes a dope fiend. The LSD user remains a lonesome user of acid, although in both cases users have to find ways to get the drugs.

In a chapter written in 1970, about drug use on campuses *Campus Power struggle: 1973* Becker takes a provocative turn, saying that the drug problem on campuses is not a drug use problem because more and more students are engaged in such a process, the campus problem is a problem of students getting caught while selling drugs or giving drugs to one another, or using drugs in the open. In his opinion, which he repeats several times, the use of marihuana is harmless and one of his proposals is to teach students how to take drugs secretly without getting caught. His provocative position led to several letters from psychiatrists and physicians saying that the results of experiments and clinical observations were not clear about the harmlessness of marihuana, and the problem of addiction was still an open question.

Art Worlds

It seems that *Art Worlds* is Becker's hidden sociological interest, he has written that at first he wanted to be a musician and then he became a sociologist. This book (Becker, 1982) is related to his first achievements in music and to that lifelong passion. The world of arts is a world in which the borders are not very clear, the differences between what is art and what is not art is quite difficult to draw, especially with the motion pictures. Becker invites us to look at the artistic process, the craftsmanship needed, the division of labor, which exists as in any other profession. Artwork is a whole world not only in the case of the symphonic orchestra, which involves instrumental techniques and the Opera building where the music is performed. It can be even for a Quattrocento painter a contract between the client and the painter, in which it is said which kind of blue he has to use, if he is allowed to use gold paint and who is going to paint the portraits. With this example in mind we may understand that painting in Holland or in Florence is not only craftsmanship but also belonged to Renaissance capitalism. Art worlds follow standards, norms, and conventions of societies; most of Becker's examples refer either to music, literature, film, painting and artistic photography, and poetry. Even if there are a few references to the Renaissance in Europe, the main topics relate to twentieth-century America. To sum up the author's position: the world of arts is a world of action, characterized by a division of labor, it is a social world, arts and crafts being complementary and exchanges between popular art and arts can be found.

In one of his most quoted chapters on *Integrated professionals, mavericks, folk artists and naïve artists*, which compares integrated professionals, on the one hand and, an American maverick Charles Ives on the other, Ives writes unplayable music that was only performed after 20 years. Much of his music was not finished. An example is the *Concord Sonata*; Ives changed his mind so many times that one may think he is unable to choose between several resolutions. This was certainly a psychological trait of the author, but with this example Howard Becker wants us to understand that the creative process needs *form*. As Georg Simmel (Simmel, 1918) had already mentioned, form is only part of the process in the art world, art works have still to go through conventions, editing, and performance in order to exist as such. The *salon des refusés* (exhibition of rejects) in painting gives a more immediate view of its achievements compared to music, which needs to be performed in order to exist.

Folk and naïve artists do not belong to the art world, but some of their works might become examples of aesthetic achievement. Quilt making is craftsmanship and belongs to American community work and American community togetherness. Some quilts are in native craft museums, but some seem to belong to the same art movement as nonfigurative painting. Where does the design come from? No one knows, it seems to follow channels of women's gatherings and visiting and moves from one community to the other. Certain geometric designs have names such as 'drunkard's path,' 'mill wheel,' 'log cabin' all tend to have an optical effect with small pieces of material cut the same size and stitched on a frame. Some of those quilts have in Gestalt language a good form but they always belong to the applied arts. This comparison shows the distance with the conventional art world although some quilts could enter in one of Raymonde Moulin's serial art categories (Raymonde Moulin, 1992). Idiosyncratic style is even more relevant in the Naïve art form of Grandma Moses' or *Facteur Cheval*. Naïve art, such as

the Watts Towers in Los Angeles, or the Ideal Palace of the postmaster Ferdinand Cheval in Southern France, is a totally individual performance. Art is performed as a hobby, as a passion, even as an obsession but without any knowledge of craftsmanship. With stones, garbage pieces, junk, the artist is giving a second life to cans, bottles, pebbles, etc. Thus a new usefulness is given to these items, the stones of Facteur Cheval now belong to a very popular castle. Naïve art has developed in many different directions, it is always far from professional training and art conventions, it may however enter the art world if an artist or a journalist is interested, although the gate is always narrow.

Howard Becker takes a comparative stance in order to answer the question what is art and what is not art. We understand that the art world is above all a technical and professional world, but it can be interested in applied arts and naive artists. Being as Charles Ives on the margin of art world, it is difficult, especially in music, to fully enter the art world and it needs a process of recognition. Those who do not belong to the world of arts such as the quilters or the naive artists maybe recognized by chance, as long as their artwork belongs to the *Zeitgeist*. Finally, Becker comes to the conclusion that art worlds can be compared to any occupational world in which changes may occur. Changes occur in Arts and in the World, rock and roll music changed not only teenagers' music but created new possibilities for music in general. One of the last questions the author asks is: What is lasting? The answer to that question cannot be simple and is usually formulated by historians and archaeologists.

Cases

What is a case? Becker answers the question in writing the introduction to the Jack Roller's own story (Shaw, 1966). A life story is a piece of a mosaic, related to many other stories such as Chicago's West Madison area which is related to N. Anderson's stories about hoboes, the high life. The boys experience is also related to Walter Reckless's *Vice in Chicago* (Reckless, 1969) or to Paul G. Cressey's *Taxi Girls* (Cressey, 1969). When Stanley goes to prison the reader thinks about Saul Alinsky who worked several years with youngsters in jail and learned to know the members of the gang he was to study later and to handle the specific language of the gangs (Guth, 2013). Becker relates the Stanley's experience of prison to the ceremonies of degradation described by Erving Goffman (1961). In that sense Chicago's sociology was a study showing the mosaic of the urban areas.

To sum up this work, one can understand that a case is only one element of the social lives lived in the slum areas and it should be compared with other cases and especially with negative cases. Thus the researcher would be able to apprehend the processes of causation and life action. The labeling theory mentioned above has shown how from one step to the other, a new behavior, identity, group control, and conformity induces personal and social changes. Biographic material is the only way of demonstrating how time matters for the individual and how the different adjustments occur. The case is of course the person's own story, the story that might be told in different ways and from different points of view. As Becker adds in his conclusion: one of the better services rendered by the life story is a public service, it gives some insight about social problems to the readers, and as such one may understand what the life of a youngster can be in the slums, particularly if he comes from a totally different background.

Howard Becker's work is not limited to sociology and he uses different tricks or artifacts in order to help us understand what society is like. It can be shown in a movie, in a painting, in a photograph, or in a play: sociology is, in a sense, a representation of society. Usually representation is given by statistics, charts, and maps, but since Jacob L. Moreno (1953), one is allowed to view it in terms of characters on stage in an interaction process.

Behavior Analysis, Applied

Ruben Ardila, National University of Colombia, Bogotá, Colombia

Abstract

One of the main developments of applied psychology during the last decades is applied behavior analysis (ABA). ABA employs basic behavioral processes, research methods, and derivative procedures, in order to prevent and alleviate problems of social importance. ABA is accountable on seven dimensions: (1) its procedures are applied to problems of relatively immediate social importance; (2) its behavioral measures are valid and reliable; (3) its procedures are described in sufficient technological detail for replication; (4) its research methods are analytic; (5) its effectiveness is socially significant; (6) its generality is demonstrated across time, settings, and behaviors; and (7) it is relevant to an overall conceptual system of behavior. This article describes the foundations of ABA, its relations to basic research, and the main areas of application, both traditional and nontraditional: behavior analysis applied to clinical problems; behavior analysis in education; industrial/organizational behavior analysis; community behavior analysis; forensic applications of behavior analysis; sport psychology and behavior analysis; violence, racism, productivity, sexism, drug abuse, and other social issues. Innovative procedures and techniques will be pointed out in this article.

Definition

Applied behavior analysis (ABA) has been defined as the application of the methods, procedures, and techniques derived from the experimental analysis of behavior (EAB) to a wide range of clinical and social institutions. The main assumption of behavior analysis is that behavior is a function of its consequences. Environmental variables are utilized in order to produce behavioral changes. A wide range of intervention techniques has been developed based on the principles of laboratory research, such as stimulus control, reinforcement, extinction, and punishment.

In the context of ABA, the term 'behavior,' is interpreted broadly to include overt responding and also covert responses (cognitions, emotions). Behavior is defined as everything that the organism does or says, in the case of human beings. Behavior is a broad term, with different ways of being interpreted. ABA includes muscular contractions, visceral secretions, cognitive factors, emotional responses, language, and social behavior.

ABA is mainly associated with operant ('Skinnerian') psychology. The term is contrasted with behavior therapy, behavior modification, behavioral engineering, cognitive behavior therapy, multimodal therapy, social learning, and others. The differences are in some cases just a matter of terminology, and there is not complete consensus in relation to the use of each term.

In ABA, the emphasis is on a body of experimental work dealing with the relationships between changes in the environment and changes in the subject's responses. Great importance is given to the experimentally established procedures and principles. The applications to socially relevant issues are considered to be derived from basic laboratory research. Clinical problems are studied by means of experimental research studies.

The model of ABA is psychological rather than medical. The emphasis on behavior (maladaptive in the case of clinical populations) implies that the therapist is not interested in underlying or disease factors that 'cause' the symptoms. In the case of clinical or maladaptive behavior, the term 'behavior therapy' centers on behavior that is observable and definable.

ABA can be traced back to several conceptualizations and experimental strategies. Particularly important is the Skinnerian analysis of behavior, leading to behavioral shaping, token economies, and environmental design. The emphasis upon the application of experimental methodology to individual cases is a distinctive feature of ABA. Social learning, modeling, and classical conditioning procedures are also taken into account.

It is possible to state that the main techniques used in ABA are operant conditioning, extinction, systematic desensitization, modeling, self-control procedures, and techniques for the modification of cognitions – a wide range of procedures that are tailored to the particular individual, the specific situations, and the behaviors to be modified.

From Laboratory to Applications

The natural science from which ABA is derived is behavior analysis. It comprises three subdisciplines: the EAB for basic research elucidating fundamental behavioral processes; ABA for the application of these processes, derivative technologies, and research methods for clinical and community problems; and the conceptual analysis of behavior, for historical, philosophical, theoretical, and methodological investigations.

The EAB involves conceptual analysis as a matter of course, that is, ontological assumptions. The EAB seeks: (1) to describe functional relations between classes of responses and classes of stimuli, and (2) to demonstrate the reliability and generality thereof, and thus their lawfulness. The dependent variable is the probability of an organism's response as a function of independent variables, which occur in real time. (Arantes et al., 2012).

On the other hand, ABA employs basic behavioral processes, research methods, and derivative procedures, in order to prevent and alleviate problems of social importance. ABA has derived from the EAB with their procedural emphases of reinforcement, punishment, and discriminative-stimulus contingencies as behavior-analytic environmental variables, their reliance on single-subject designs as the formats of analysis and proof, and their consistent use of the Skinner box as

their arena (Kazdin, 2000). On the other hand, in the last decades ABA has been characterized by seven key terms: applied, behavioral, analytic, technological, conceptual, effective, and capable of appropriately generalized outcomes.

The importance of a conceptual analysis has been pointed out since the beginning of the EAB. The conceptual analysis includes metatheory and philosophy, history and historiography, methodology, and system and theory.

History of the Area

ABA began in the 1950s. The first decade was characterized by polemics and paradigmatic clashes. The second decade was the time of consolidation. The third saw the development of a refined methodology and new conceptual models. The most recent period has been characterized by applications to new fields, even in the so-called nontraditional areas (Mattaini and Thyer, 1996; Cooper et al., 2007; Madden, 2012).

A very relevant problem refers to the role of conditioning in ABA and in behavior therapy. This area was sometimes called 'conditioning therapy,' and it was considered as the application of the laws of 'modern learning theory.' Discussion has arisen concerning the differences between conditioning in the animal laboratory, in the clinic, and in daily life. Conditioning as the explanatory foundation of all ABA has been very controversial. Some authors have insisted on the need to include knowledge drawn from psychobiology and social psychology, instead of relying only upon conditioning-learning theory.

The role of cognition in ABA has been a central topic of discussion. Due to the desire to eliminate all reference to mentalism and to inner processes, early behavioral analysts rejected all forms of cognitive influence. But in the 1980s the 'cognitive revolution' led to some reformulations and reconceptualizations, and there was discussion about the role of cognition in behavior change. The term 'cognitive behavior therapy' was used, rather than just behavior therapy. However, if behavior includes cognitive processes, the addition of 'cognitive' is redundant. The controversy continues during the second decade of the twenty-first century, and several positions and disputes exist concerning this issue. The precise relationship between behavior and cognition remains equivocal (Ardila, 2010).

Techniques

A large number of techniques have been developed in the area of ABA. Some of them are based on operant conditioning, others on classical conditioning, social learning, or a combination of them. Some involve principles derived from social psychology, developmental psychology, physiological, and cognitive psychology. Only the main techniques is presented here, and the list is not exhaustive.

Systematic Desensitization

This is a term applied to a class of methods used for gradually weakening maladaptive anxiety response habits through the use of responses that compete with anxiety. As an example, a physiological state inhibitory of anxiety is produced in the patient by means of muscle relaxation; the patient is then exposed for a few seconds at a time to a stimulus arousing weak anxiety. With repetition of the exposure, the stimulus progressively loses its ability to evoke anxiety. In a progressive way, stronger stimuli are presented.

The standard procedure in systematic desensitization consists of several sets of operations: (1) introduction to the subjective anxiety scale, (2) training in deep muscle relaxation, (3) construction of anxiety hierarchies, and (4) counterposing relaxation and anxiety-evoking stimuli from the hierarchies.

Counterconditioning is the basis of the change that follows systematic desensitization, according to Wolpe (1958), other researchers and clinicians.

Biofeedback

This term refers to a number of clinical techniques, which provide feedback to patients concerning changes in a particular physiological response, so that they can learn to modify the physiological response. Two methods of providing information feedback to the patient have been developed: binary feedback (yes/no information) and analogue feedback (proportional). A number of physiological responses have been shown to be modifiable using biofeedback. The most common physiological responses to be used clinically are electromyogram activity, skin temperature, blood pressure, electro-encephalogram, vasomotor, and heart rate.

Biofeedback is used in lowering the blood pressure of essential hypertensives, for achieving relaxation, for epilepsy, migraine headaches, and many other clinical problems.

Punishment

Punishment is an operant conditioning procedure in which the future probability of occurrence of a response is reduced as a result of response-dependent delivery (positive punishment) or removal (negative punishment) of a stimulus (punisher). An example of positive punishment is spraying water mist in the face of a self-injurious child each time an instance of self-injurious behavior is observed. An example of negative punishment is taking an earned token from a person each time he or she curses. In the first case the aim is to reduce the occurrence of self-injury; in the second case it is to reduce the rate of cursing.

Punishment may weaken, strengthen, or have no effect on other response classes. Its effects are controversial and subject to discussion. In the early stages of ABA, punishment procedures were used more frequently than now. Alternatives to punishment are usually preferred.

Escape Training

In this training procedure an individual learns to perform a response in order to terminate a punishing stimulus.

Avoidance Training

This is a training procedure in which an individual learns to keep away from a designated stimulus in order to prevent

punishment. The first step consists in pairing the designated stimulus with a punisher. Then the individual is negatively reinforced by performing a response that terminates the punishing stimulus. The individual subsequently learns to prevent punishment from occurring by either responding with an alternative behavior (active avoidance) or not responding at all (passive avoidance) prior to coming in contact with the designated stimulus.

Extinction

Extinction is a response-weakening procedure, which can involve consistent failure to deliver a reinforcer following an operant response, which had previously produced that reinforcement (operant extinction). It eventually results in nearly complete elimination of the operant response, although a transient rate increase is frequently observed soon after operant extinction is arranged.

This technique is widely used in behavior modification and is preferred to punishment, avoidance training, escape training, and similar aversive procedures.

Shaping

This technique consists of reinforcing successive approximations to the desired response. Usually a simple response is required initially, and criteria for reinforcement are gradually made more stringent so as to produce more complex or refined response. Initially a simple response (in the direction of the desired goal) would be sufficient to receive reinforcement. After this behavior is performed reliably, reinforcement is given only for a more complex or difficult response. The next step consists of giving reinforcement for the slightly more complex response. The pattern continues until the final desired behavior is achieved regularly.

Contingency Management

Contingency management involves the analysis and change of the functional contingencies in the environment that determine a person's behavior. As a result, the behavior changes from its initial rate to a different rate of occurrence. In clinical work, this involves the development of new or alternative forms of adaptative behavior. Within a certain environmental context, a contingency describes a functional relationship among stimuli antecedent to a particular behavior (the target) and the consequences that follow the occurrence of the behavior.

The functional environment for a particular person is often different from the functional environment of another person. Many stimuli or events that occur in a person's environment do not have any effect on the person's behavior. In those cases we can say that the particular part of the environment is not functional, it is just present.

Contingency management involves the analysis and modification of contingencies involving discriminative stimuli, reinforcement, punishment, and extinction. It focuses on public and observable behaviors and controlling environments. The environment of interest is primarily that part which functions to increase, decrease, or control the occurrence of certain behaviors. Contingency management in clinical practice typically is concerned with appropriate discrimination and generalization of adaptative behavior changes.

After a comprehensive functional analysis of environmental contingencies, the therapist plans a program of intervention to modify contingencies to change the rate of the target behavior. Contingency management involves a thorough functional analysis of controlling contingencies, the rearranging of the functional analysis of controlling contingencies, the rearranging of the functional environment, and a careful monitoring of outcome.

Environmental Design

This consists of the application of empirically derived principles of behavior for the modification and design of the environment. It involves the planning of a coherent program and set of procedures to affect the total human and nonhuman environment in ways that increase the probability that certain goals will be achieved.

The goal of environmental design relates to social behavior, for instance, planning a therapeutic or educational system. It includes linking ABA and environmental psychology. It involves training people to conceptualize the environment so that they can apply the general principles of behavior analysis to design planning. Social design and physical design should be considered. The larger context is the planning of a whole society, such as *Walden Two* (Skinner, 1948), or *Walden Three* (Ardila, 1990).

Token Economy

In the token economy intervention, reinforcers are delivered for specific target behaviors. Reinforcers are tokens (tickets, coins, points, stars) that can be exchanged for a variety of other rewards. Tokens help bridge the delay between the person's performance of a desired behavior and delivery of a reward.

As an example of the use of token economies in complex settings we can mention the University of Kansas Experimental Living Project, a behaviorally managed experimental community of 30 college students (Johnson et al., 1991). Token economies have also been used in prisons, in nursing homes, on psychiatric wards, in normal classroom settings from preschool to university classes, on wards for the treatment of drug addicts and alcoholics, in various work settings to increase safety behavior, in community settings to increase recycling of waste and improve energy conservation, and in many other contexts.

Premack Principle

This principle says: for any pair of responses the more probable one will reinforce the less probable one. The technique derived from the Premack Principle consists of a special class of reinforcing operations in which access to high probability behaviors is made contingent upon clinically targeted activities. For instance, children may be allowed to eat candy after (contingent upon) doing their homework.

Modeling

This consists of the presentation of a live demonstration, a filmed or pictorial presentation, or an imagined one. Based on the presentation, the viewer learns a method of responding or the contingencies under which the target response will fall.

Observational learning, imitation, and modeling are terms frequently used with respect to this phenomenon. These techniques are useful in the treatment of phobias, and in forming social skills and many other desired behaviors.

Cognitive Procedures

Cognitive therapy or cognitive ABA refers to a wide range of approaches, based on two explicit hypotheses: (1) cognitive factors such as thoughts, images, and memories, are intimately related to dysfunctional behavior, and (2) modification of such factors is an important mechanism for producing behavior change.

Behavioral Self-Control

This set of techniques involves training patients to control their own behavior through the systematic use of behavior principles. The therapist educates patients regarding the technical aspects of various behavior change procedures. In a self-reinforcement program, patients are taught to administer consequences to themselves that are contingent upon the performance of the target behavior.

In the majority of cases behavioral self-control involves self-monitoring, self-evaluation, and self-delivered rewards. There are many potential benefits to teaching patients self-control rather than treatment through external agents. Self-control therapy allocates a great responsibility to patients. It is clear that teaching individuals to be their own therapists will contribute to generalization of treatment effects because patients will be able to continue to administer the program or develop new treatment following the termination of therapy.

Principal Areas of Application

ABA is a broad term and covers many fields of applied psychology, both traditional and nontraditional. A brief description of some of these areas follows.

Behavior Analysis Applied to Clinical Problems

This field is also referred to as behavior therapy, and has a long history. Behavior therapy has been defined as follows:

> Behavior therapy is the attempt to utilize systematically that body of empirical and theoretical knowledge which has resulted from the application of the experimental method in psychology and its closely related disciplines (physiology and neurophysiology) in order to explain the genesis and maintenance of abnormal patterns of behavior; and to apply that knowledge for the treatment or prevention of those abnormalities by means of controlled experimental studies of the single case, both descriptive and remedial.
> (Yates, 1970: p. 18)

Lovaas (1966, 1977, 1993) has developed behavioral treatment for autistic children. He focused on strategies to teach social behaviors, eliminate self-stimulatory behaviors, and develop language skills. The behavioral treatment has produced long-lasting effects, and no alternative treatment for autistic children has been shown to be as successful as behavior modification (Bourret et al., 2012).

Behavior Analysis in Education

A number of applications have been carried out in several important educational aspects: behavior modifications in special populations (mental retardation, visual and auditory limitations, people with physical limitations, children of superior intelligence, and so forth). Also work has been done in order to maximize the efficiency of teaching techniques, learning in the classroom, and in general academic learning from preschool to university education. The techniques of reinforcement, contingency management, environmental design, token economy, and so forth, previously described in this article, have been applied to the educational area.

Industrial/Organizational Behavioral Management

In the early 1970s ABA entered the industrial arena. At the heart of this approach lies the belief that most complex human behaviors are learned, and by altering either the conditions preceding the behavior or especially the consequences following it, that behavior can be altered and new behavior patterns can be learned. A wide variety of industrial-relevant behavior has been successfully altered: teaching the skills required for the job, motivating the performer, reducing absenteeism, reducing turnover, learning to work in groups, improving communication skills in the work setting, reinforcing adequate behavior, extinguishing undesired behavior, increasing productivity, improving morale, overcoming resistance to change, and others (Hersey et al., 1996).

Behavioral Community Psychology

As a 'marriage' of the methodology of behaviorism and the strategies and conceptual framework of community psychology, the area of behavioral community psychology (Nietzel et al., 1996) uses classical conditioning, operant conditioning, social learning, and cognitive/self-control procedures. Examples of operant behavior analysis are prompts, feedback, reinforcement, and response cost. Examples of social learning and cognitive/self-control procedures are modeling, behavioral rehearsal and role-playing, self-instruction, and self-regulation, especially with respect to the development of skills and self-help competences in target populations.

Forensic Applications

Most applications of behavior analysis to psychology and the law have been in connection with criminal justice. Work has been carried out concerning the behavior of the delinquent individual, including juvenile delinquents and predelinquents; in the prevention of criminal behavior; and in the areas of legal

processing, the courts, the jury, witnesses, and so forth. Special importance has been given to the behavior modification of delinquents using behavior analysis procedures.

Sport Psychology

In this area the contribution of ABA has been centered on motivation of athletes, athletic performance, leadership, optimal coaching strategies, audience effects, sport violence, and other similar issues. The main behavioral technology procedures used in sport psychology are positive reinforcement, shaping, chaining, extinction, time out, response cost, fading, prompting, performance feedback, self-monitoring, self-instructions, deep muscle relaxation, modeling, imaginal rehearsal, behavioral rehearsal, thought stopping, and response-induced aids (Luiselli and Reed, 2011).

Larger Sociocultural Applications

A number of 'big issues' have been addressed with the procedures of behavior analysis: youth violence, racism, sexism, poverty, health problems, destruction of the environment, the breakdown of schools, lack of productivity in the workplace, child maltreatment. According to Mattaini and Thyer (1996) these behavioral problems "could ultimately threaten the survival of the human race and other species" (p. 1).

Abstract

Behavior therapy has a complicated history and ever-changing web of intellectual allegiances and influences, including behaviorism, behavior science, cognitive science, folk psychology, and Eastern philosophical traditions, to name only a few. These schools of thought are extremely difficult if not impossible to encapsulate using a few simple properties that traverse and define every approach. Rather, behavior therapy is much more like a 'family resemblance' in which common essential properties play a role in a complex web of belief. Against this backdrop, therefore, it is the aim of this article to discuss the common essential properties related to the conceptual and theoretical background, basic principles and learning processes, and early history of first-generation or first-wave behavior therapy. The first-wave behavior therapists include such prominent figures as Joseph Wolpe, Ogden Lindsley, Nathan Azrin, and Hans Eysenck, to name only a few. The so-called 'second-wave' and, perhaps, 'third-wave' behavior therapy will be taken up in article Behavior Therapy: The Second and Third Waves.

It is hard to envision the field of behavioral health before behavior therapy, considering its effectiveness and its pervasiveness in so many health care arenas. But before the advent of behavior therapy, a variety of schools of psychoanalysis had the greatest clinical following (Eysenck, 1952). These had the widest application in the treatment of various neuroses or neurotic tendencies like phobias and anxiety-driven compulsions (David-Ménard, 1989). However, despite the widespread adoption, these could offer little by way of treatment for such chronic conditions as schizophrenia and autism. In addition, these offered little data to support their efficacy and were not particularly efficient – often being applied for years or decades if the client was willing and had sufficient resources. Psychoanalysis advanced the, perhaps, iatrogenic notion that pathology resulted from ego impairment due to inadequate child rearing (Kanner, 1943; Mahler, 1968; Tustin, 1981).

Unfortunately, these parent–child relationship theories had a devastating impact on many families – especially with the assertion of the so-called 'refrigerator' mothers who were ultimately held accountable for their children's abnormal development (Willick, 2001). Fortunately, particularly in the United States, psychoanalytic views of mother–child attachment dysfunction have been supplanted by more empirically substantiated behavioral theories (Eldevik et al., 2009; Patterson et al., 2010). Only the most ardent proponents of psychoanalysis would now claim that neurodevelopmental disorders are caused by a patient's relationship with his or her mother – at least in North America and throughout much of Europe (*see* Psychoanalysis: Current Status for a thorough discussion on modern psychoanalysis).

Behavior therapy developed, in part, out of dissatisfaction with psychoanalysis in treating certain types of intractable, chronic psychiatric conditions. Part of the dissatisfaction was simply due to the lack of outcome data meeting minimal scientific standards. Part of the dissatisfaction was based on the notion that what data were available at the time did not point to large treatment effects (Eysenck, 1952). And part of the dissatisfaction was due to what were seen as problems with psychoanalytic theory more fundamentally – vague constructs, unclear measurement operations, unclear predictions, and warring factions within psychoanalysis that could not agree on fundamentals.

Of course, behavior therapy was not the only contender vying for psychoanalysis' seat in mental health practice. Carl Rogers's client-centered therapy and other humanistic theories also emerged out of dissatisfaction with psychoanalytic approaches (Rogers, 1951). Like psychoanalysis, however, client-centered therapy was not without its critics. Among other things, client-centered therapy, too, has been criticized for its vagueness of principles, its disregard for diagnosis and hence any modifications for specific problems, and its emphasis on the client's self-evaluation as the principal way to assess therapeutic outcomes (Carter, 1948; Hathaway, 1948; Louttit, 1948). Regarding the last point, self-evaluation is almost always the principal challenge in persons with personality disorders, e.g., borderline personality disorder, schizotypal personality disorder, histrionic personality disorder, and narcissist personality disorder. Accordingly, if left to their own devices, patients with personality disorders and virtually everyone around them would likely perceive the same clinical outcome quite differently. For example, what might be regarded as a treatment success for someone with narcissism might be deemed a treatment failure for a family member who has routine contact with him or her.

Behavior therapy, in contrast, is based on very different assumptions. According to Goldberg, there are 10 underlying assumptions of behavior therapy (Goldberg, *Family Therapy*, 1996: p. 254).

1. All behavior, normal or abnormal, is acquired and maintained in identical ways (that is, according to the same principles of learning).
2. Behavior disorders represent learned maladaptive patterns that need not presume some inferred underlying cause or unseen motive.
3. Maladaptive behavior, such as symptoms, is itself the disorder, rather than being a manifestation of a more basic underlying disorder or disease process.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21054-4

4. It is not essential to discover the exact situation or set of circumstances in which the disorder was learned; these circumstances are usually irretrievable anyway. Rather, the focus should be on assessing the current determinants that support and maintain the undesired behavior.
5. Maladaptive behavior, having been learned, can be extinguished (that is, unlearned) and replaced by new learned behavior patterns.
6. Treatment involves the application of the experimental findings of scientific psychology, with an emphasis on developing a methodology that is precisely specified, objectively evaluated, and easily replicated.
7. Assessment is an ongoing part of treatment, as the effectiveness of treatment is continuously evaluated and specific intervention techniques are individually tailored to specific problems.
8. Behavior therapy concentrates on the 'here and now' problems, rather than uncovering or attempting to reconstruct the past. The therapist is interested in helping the client identify and change current environmental stimuli that reinforce the undesired behavior, in order to alter the client's behavior.
9. Treatment outcomes are evaluated in terms of measurable changes. Research on specific therapeutic techniques is continuously carried out by behavior therapists.
10. Research on specific therapeutic techniques is continuously carried out by behavioral therapists.

The first generation or 'first wave' of behavior therapists developed out of experimental work in the laboratory with animals (O'Donohue, 2009). Between the 1940s and the 1950s, behavior therapists presented better, although often still flawed, empirical evidence on a number of clinical problems that eluded traditional therapies of that era, like schizophrenia and autism. For several decades, there was a proliferation of applied behavioral research, which applied these principles of behavior in earnest to countless clinical problems. In fact, Lindsley and Skinner – in what some regard as the first use of the term behavior therapy – successfully treated an electively mute schizophrenic woman (Lindsley and Skinner, 1954). Mowrer and Mowrer (1938) reported similar, dramatic improvements in treating enuresis in residential settings for developmentally delayed persons (*see* Behavior Analysis, Applied for a discussion on applied behavior analysis).

Before proceeding, some clarification about this notion of generations or waves is warranted. These notions are not akin to scientific revolutions as seen in basic science (cf physics, biology, or chemistry; Kuhn, 1962; Lakatos, 1970, 1978; Popper, 1959, 1962, 1972). The older paradigm is not replaced. Rather, these waves seem to be additive. For example, the first wave continues to this day in the field of applied behavior analysis (ABA), especially in the treatment of patient populations with highly limited behavioral repertoires such as those suffering from autism (e.g., ABA is still considered the gold standard for autism therapy). The second wave will be taken up in Behavior Therapy: The Second and Third Waves. Likewise, few would argue that cognitive behavior therapy has appreciably declined in popularity among therapists despite the emergence of a large interest in what some authors suggest as third-wave therapies (Hayes, 2004; Hayes et al., 2006). So-called third-wave therapies will be discussed in Behavior Therapy: The Second and Third Waves as well.

The purpose of this article is to provide an overview of the conceptual and theoretical background, basic principles, and early history of first-generation or first-wave behavior therapy. Readers should note that the authors define behavior therapy broadly to include behavior therapy, cognitive therapy, cognitive behavior therapy, and behavior analytic or contextual behavioral science as some would have it. The authors acknowledge that the heterogeneous nature of behavior therapy may make this broad definition too generic. Nonetheless, the present state of the literature does not allow for a more specific definition or paradigm, as the field has yet to come to a consensus about what behavior therapy actually is.

Brief History and the Principles of Behavior Therapy

The first wave extended the core principles of behavior discovered in the learning laboratory to many socially relevant problems in the decades that followed (O'Donohue, 2009). Two of the most influential figures during the first wave were Ivan P. Pavlov and B.F. Skinner.

The Russian physiologist, Pavlov, identified several basic learning mechanisms in the early twentieth century: habituation/sensitization and classical conditioning processes (Pavlov, 1927, 1928). Habituation and sensitization are the most fundamental types of behavioral processes (nonassociative or perceptual learning). They involve a two-term relation between stimulus and response (S-R). In the case of habituation, repeated presentations of an eliciting stimulus (i.e., S) result in a decrease in response (R) magnitude. Pavlov, for example, noted that the orienting reflex in subjects diminished over time in the experimental apparatus. Clinically, in humans, the 'white coat effect,' or increased blood pressure during office visits in patients whose daily ambulatory blood pressure is otherwise normal (i.e., $<120/<80$ mm Hg), illustrates this behavioral principle (Chrysant, 2000). Such patients are often asked to sit in the examination room for longer durations until their physiological distress has diminished (conditioned response (CR)) with increased exposure to medical stimuli (conditioned stimuli (CSs)).

Sensitization, in contrast, results in an increase in response (R) magnitude with repeated presentations of an eliciting stimulus. Generally speaking, sensitization results from presenting stimuli like loud noises, painful shock, or bright lights. A learning history involving intermittent shock, for example, might increase the orienting response to novel environments, as the organism might be more likely to engage in defensive responses. Likewise, humans with a history of trauma (i.e., high-intensity aversive stimuli) may display hypervigilance or an exaggerated startle response when introduced to novel environments (ApA, 2013).

Pavlov also demonstrated that neutral stimuli that produce no change in responding can be potentiated when paired with or associated with a biological reflex (i.e., unconditioned stimulus (US)). In the four-term relation

in classical conditioning (CS–US–UR–CR), the neutral stimulus, CS (e.g., an auditory or visual stimulus), is paired with a US (e.g., food or shock). Through repeated presentations, the CS will come to elicit responses *similar* to the UR (unconditioned response). Although topographically similar (e.g., salivation or pupillary reflex), the CR may differ from the UR with respect to magnitude and latency (i.e., the time it takes to elicit the response following the presentation of the stimulus). The CS can also serve an *excitatory* or *inhibitory* function, signaling the presence or absence of the US, respectively. This process is called stimulus discrimination (Pierce and Epling, 1999). Again, persons with a history of trauma may show an intense or prolonged physiological distress when exposed to internal or external cues (i.e., the CS serves an excitatory function) that were paired with certain aspects of the traumatic event (ApA, 2013). Some Vietnam veterans, for example, display intense physiological distress when smelling gasoline (which, reportedly, smells similar to napalm), and/or upon hearing fireworks on the 4th of July or helicopters hovering overhead (*see* Classical Conditioning Methods in Psychotherapy for a further discussion on classical conditioning).

John B. Watson and Rosalie Rayner were the first researchers to explore Pavlovian or classical conditioning processes in human subjects. Extending Pavlovian principles to human subjects, Watson and Rayner examined classical conditioning processes in a landmark study involving an 11-month-old baby (Watson and Rayner, 1920). During baseline, the infant freely played with a white rat, demonstrating no significant fear behavior. By repeatedly pairing the rat (CS) with a loud noise (US), however, the infant started showing fear and would escape the stimulus whenever it was present.

Expanding on Watson and Rayner's work, Mary Cover Jones (1924a,b), showed the reverse through the process of counterconditioning: by repeatedly pairing the feared object (CS) with a different stimulus associated with a positive stimulus or having the child who feared the stimulus associate with children who did not show the characteristic fear response while in the presence of the feared stimulus. The process of counterconditioning (or respondent extinction), of course, is the fundamental principle behind the treatment now known as exposure and response prevention (Foa and Kozak, 1996) (interested readers should consult Exposure Therapies and Stress Inoculation: A Brief Overview for a discussion on exposure therapies). Of course, while necessary, the process of counterconditioning is not sufficient for conceptualizing most anxiety conditions that present clinically. Anxiety conditions are often more complex than can be addressed by basic respondent processes.

Mowrer's (1947; 1951; 1956) two-factor theory of emotion has been the most influential theory of fear and avoidance even to this day. The two-factor theory of emotion is based on the work of Hull (1943), though unlike Hull, Mowrer explained conditioned or learned fear by way of classical conditioning processes (recall Hull's drive reduction theory). Namely, CSs are first paired with aversive unconditioned stimuli (USs) until there has been adequate transfer of function(s) (i.e., the CS elicits the characteristic response associated with the US). Based on this model, individuals with this conditioning history will emit overt behavior in the service of terminating the CS rather than avoid the US.

Individuals with posttraumatic stress disorder (PTSD) illustrate this point very well. Internal or external reminders of a traumatic event (CSs) might be avoided for years – even decades after the threat has subsided (e.g., it is very unlikely that debris on the side of the road in Salt Lake City is an improvised explosive device) (*see* Post-Traumatic Stress Disorder for an in-depth discussion on PTSD). Sadly, many veterans of war, who have seen combat, seldom leave their homes (avoidance behavior), as stimuli in the community (e.g., crowds, work crews, loud music, and planes overhead) often elicit intense fear.

Despite interest in these early experiments, clinicians were slow to adopt these principles of behavior in routine practice, still opting for psychoanalytic paradigms. By the 1940s and the 1950s the tide was starting to turn, however; behavior therapy was on the rise in South Africa (Joseph Wolpe), England (Hans Eysenck), and the United States (Ogden Lindsley). Interestingly, as pointed out by Öst (2008), these researchers developed their ideas almost independently of one another.

Wolpe based his treatment, systematic desensitization, and theory of reciprocal inhibition on the work of Pavlov (Wolpe, 1958). Systematic desensitization is a counterconditioning strategy designed to treat "neurotic-anxiety response habits" (Wolpe, 1990: p. 150). Through systematic desensitization, the therapist induces a deep state of relaxation throughout graduated exposure to a feared stimulus as it is believed to reciprocally inhibit and thus weaken learned anxiety habits (Wolpe, 1976). In treating a snake phobia, for example, one would have the client continue to relax at every successive approximation which, ultimately, eventuates in actually handling the snake.

Wolpe marshaled many studies demonstrating the efficacy of behavior therapy in the treatment of phobias and other anxieties (Poppen, 1995). Wolpe, arguably, spearheaded the modern behavior therapy movement, as his work established a sustainable program of research that had a notable impact on how clinicians practiced (O'Donohue, 2009). In fact, to this day, therapists continue to use Wolpe's therapeutic approach. Stress inoculation therapy is one such example, which has helped countless patients undergo highly distressing medical procedures (Meichenbaum, 1985; Meichenbaum and Deffenbacher, 1988; Meichenbaum and Jaremko, 1993).

Since Wolpe's time, classical conditioning mechanisms have played a central role in understanding the development of fear and other anxiety disorders (e.g., PTSD, panic disorder), in the two-factor theory of emotions (Mowrer, 1951, 1956) and more contemporary theories such as Barlow's alarm theory (Barlow, 1988). Respondent extinction (i.e., the eliciting of the CS without the UCS) is the hallmark intervention of Wolpe's systematic desensitization and in more contemporary approaches.

At around the same time in England, Eysenck's work on hysteria and anxiety was largely influenced by the drive reduction theory of Hull and Spence (Hull, 1952; Spence,

1956). Eysenck saw personality traits as being inherited and due to learned behavior. He saw the personality trait of neuroticism – a susceptibility to the effects of stress and anxiety – principally due to an individual's learning history (1967, 1994). Accordingly, treatment would therefore entail providing new learning opportunities to counter an individual's learning history.

In the United States, Lindsely applied operant techniques, developed in the laboratory of B.F. Skinner and colleagues (Ferster and Skinner, 1957; Skinner, 1938, 1953), to patients with extremely limited behavioral repertoires (e.g., patients with schizophrenia and severe mental retardation (Barrett and Lindsley, 1962; Lindsley, 1956, 1959, 1960; Mednick and Lindsley, 1958; Lindsley et al., 1953)). Among his many accomplishments, Lindsley is best known for applying operant methods to treating chronic schizophrenia (Lindsley, 1956).

Skinner coined the term 'operant' because responding is said to operate on the environment – roughly, change it – to produce certain consequences (Skinner, 1953). The consequence in turn exerts influence on the behavior that produced it (Skinner, 1957). Behavior thus increases, decreases, or maintains at its present level of intensity and frequency following the associated consequence(s). The behavior is believed to be caused by the consequence and this causal relationship between the environment and behavior is called a contingency (Sulzer-Azaroff and Mayer, 1991: p. 251). Skinner thought this capability had origins in the evolutionary history of the species and was akin to selection at the biological level (Skinner, 1953).

The three-term contingency is the simplest conceptual model of operant conditioning processes (Holland and Skinner, 1961). The three-term contingency consists of a discriminative stimulus (antecedent stimulus, S^D), behavior, and the consequences of behavior (Catania, 1992). According to this model, discriminative stimuli in the environment occasion or evoke a given class of behavior (a class is determined by the function of behavior). Certain behaviors are therefore more or less likely to be emitted in the presence of various discriminative stimuli. Discriminative stimuli are potentiated by being frequently paired with reinforcers. Responding comes under stimulus control when discriminative stimuli differentially increase the probability of a class of behaviors under characteristic environmental conditions, while decreasing the probability of other responses that are unrelated to the prevailing contingencies of reinforcement (Michael, 1993). For example, when selections are illuminated on a soda machine, the illuminated choices serve as discriminative stimuli, as placing the required money in the vending machine and making the selection will likely result in the selected item. The illuminated selections are potentiated by being paired with the consequences of (1) delivering the soda (conditioned reinforcer) and, ultimately, (2) consuming the soda (primary reinforcer).

Insofar as an S^D increases the probability that a given operant will be emitted by an organism, an S-delta (S^Δ) decreases the likelihood of responding (Pierce and Epling, 1999). An S-delta signals that a reinforcer will not follow behavior in its presence (signaling extinction). Using the example above, an out-of-order sign signals that placing money in the vending machine will not eventuate in the desired item. The behavior of placing coins in the vending machine in the presence of the out-of-order sign becomes extinguished in short order.

Aversive stimuli can also enter into a contingency. An operant that removes an aversive stimulus is called escape. A person with a needle phobia, for example, might escape the CSs of the doctor's office that are associated with having one's skin poked (unconditioned stimuli, UC; Mowrer, 1947, 1951, 1956). An operant that prevents contact with the aversive stimulus is called avoidance. The same individual might avoid going to the doctor for well visits entirely. In either case, the most critical feature is that the stimulus is added to the present environment and removed or prevented contingently after a certain behavior is emitted. Over time, if the behavior maintains at its current level or increases in regard to intensity and/or frequency, the escape or avoidance behavior is said to have been negatively reinforced. The escape or avoidance behavior of persons with agoraphobia, for example, has been negatively reinforced. The behavior of a person with a specific phobia that either escapes or avoids the aversive stimulus is similarly negatively reinforced.

Behavior may decrease in intensity and/or frequency by adding an aversive stimulus or stimuli to the current environment or taking something away. When contingent behavior decreases in frequency in response to something aversive being introduced into the environment, the behavior is said to have been positively punished. This principle is also referred to as Type I Punishment in the applied literature (Foxx, 1982). The reduction of positive punishment (e.g., criticisms, nagging, yelling, etc. – if these consequents eventuate in a reduction in behavioral intensity or frequency) plays a central role in integrative behavioral couple therapy (Jacobson and Follette, 1986). Problematic relationships, for example, invariably entail skewed ratios where negative comments from partners greatly outweigh positive ones.

When contingent behavior decreases in frequency in response to taking something away, negative punishment is said to be operating on behavior. Negative punishment is also called Type II Punishment, or response cost in applied circles (Sulzer-Azaroff and Mayer, 1991). Returning to the couples' example, the 'silent treatment' is one such example, as it invariably follows behavior that one partner finds distasteful or unpleasant (readers should consult Principle of Reinforcement for a further discussion on the principle of reinforcement).

It is important to note that other learning processes were also studied and applied. Conditioned inhibition, latent inhibition, operant–respondent interactions, choice, behavioral economics, optimization, adjunctive behavior, learned helplessness, rule-governed behavior, stimulus equivalence, observational learning, among other phenomena were studied in the laboratory and applied to clinical phenomena (Catania, 1992; Pierce and Epling, 1999). However, despite advancements, it seems fair to say that as the technical nature of learning phenomena increased, the interest or ability to apply it to clinical

phenomena decreased. This phenomenon could also partly be responsible for the rise of second-wave behavior therapy, which will be taken up in article Behavior Therapy: The Second and Third Waves.

Conclusions

Cognitive behavior therapy has a complex history and an ever-changing web of intellectual commitments and interests. It is difficult or impossible to characterize by a simple definition that attempts to enumerate a few essential properties. Rather, it is much more like a Wittgenstein (1952) 'family resemblance' in which common essential properties play a central role in a complex web of belief (Quine and Ullian, 1970). This article discussed the essential properties related to the conceptual and theoretical background, basic principles and learning processes, and early history of first-generation or first-wave behavior therapy.

Behavior therapy developed out of dissatisfaction with psychoanalysis in treating certain types of intractable, chronic psychiatric conditions. Even though it proved highly effective in treating a number of clinical conditions that had eluded clinicians for decades, practitioners eventually perceived limits with the first wave of behavior therapy. Perceived shortcomings in treating certain patient populations – especially higher functioning patients – gave rise to the second wave of behavior therapy. The second wave will be taken up in article Behavior Therapy: The Second and Third Waves.

Abstract

Behavior therapy is inextricably tied to the health care environment and its practice is subject to the same market forces as other therapeutic orientations like psychoanalysis and psychodynamic therapy, humanistic therapy, and theoretical eclecticism. Of course, as most practitioners who have had to navigate through current procedural terminology (CPT) codes and countless insurance plans would attest, the health care arena is changing at a blistering pace. Given a strong commitment to empiricism (at least ostensibly), behavior therapists are especially well posed to survive, and perhaps, even flourish in a constantly changing health care market, which is only becoming more complex and demanding as health care costs rise while Medicare and Medicaid dollars continue to dwindle. This article provides a general overview of evidence-based practices in psychology, specific examples of behavioral approaches to clinical disorders, and several important unresolved issues, which touches on possible reasons why behavior therapy's growth seems to have slowed considerably since its inception over half a century ago.

Behavior therapy does not exist in a vacuum. Behavior therapy, rather, exists within a health care environment that is constantly evolving. Behavior therapy, unlike other areas in psychotherapy (e.g., psychodynamic approaches) is, arguably, best suited to work within the health care environment of the future, considering its pragmatic aim and commitment to empirical science. The market increasingly wants to buy evidence-based assessments and interventions that have been shown to be effective and safe. Among other things, insurance carriers are most concerned about the 'bottom line' as captured in Gordon Paul's (1967) oft-quoted remark: "What treatment, by whom, is most effective for this individual with that specific problem, under which set of circumstances" (p. 44). Behavior therapy can readily answer this question, unlike other approaches that are more nebulous like insight-oriented approaches. Moreover, behavioral approaches also lend themselves well to continuous quality improvement, which is pervasive in the ever-evolving health care market (Leonard et al., 2004) (*see* Managed Care and Psychotherapy in the United States for a discussion on the impact of managed care on psychotherapy in the United States).

Behavior Therapy and Evidence-Based Practices in Psychology

Clinical practice guidelines (CPGs) were introduced into the medical community several decades ago. These guidelines were designed to assist health care providers in clinical decision-making and attempted to nudge clinicians toward standardization of practice (Shekelle et al., 1999). An emphasis on empirical research and standardization served toward quality improvement of medical surgical services by reducing treatment variability among providers (Carnett, 1999; Handley et al., 1994). Most importantly, through standardization and its minimization of unwanted variance, medical errors could be reduced, thus obviating iatrogenesis, patient morbidity, and mortality (e.g., dispensing the wrong medicine).

The American Psychiatric Association (APA) began drafting their own CPGs in 1991 to assist providers in managing the care of persons with psychiatric illnesses (APA, 2006). Naturally, the emphasis of APA's guidelines were on psychotropics, not nonpharmacological approaches like psychotherapy despite the fact that those approaches were either comparable or superior for certain clinical conditions (Barlow, 1996). Comprised of a panel of about a dozen experts, the American Psychological Association assembled a task force of its own to promote nonpharmacological approaches: Division 12 Task Force on Promotion and Dissemination of Psychological Procedures (Chambless et al., 1998).

Among other things, the Task Force bifurcates efficacious therapies into two groups: 'Well-established treatments' and 'probably efficacious treatments.'

Well-established treatments. Well-established treatments meet the following criteria (I or II, III, IV, and V):

I. At least two good between group design experiments demonstrating efficacy in one of two ways:
   A. The treatment in question is statistically significant to a placebo condition (pill or psychological) or to another treatment.
   B. The treatment in question is equivalent to an already established treatment in experiments with adequate sample sizes.
   or
II. More than a series of nine single-case experiments demonstrating efficacy. These experiments must employ a good experimental design and compare the intervention in question to another placebo or treatment, as is the case in I.A.
III. Experiments must utilize treatment manuals.
IV. Participant characteristics must be explicitly stated.
V. Results must come from at least two different research teams.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21091-X

Probably efficacious treatments. Probably efficacious treatments share criteria IV and V though differ with respect to criteria I–III.

I. Two experiments that demonstrate that the treatment in question is statistically significant to a waiting list control group.
or
II. One or more experiments meeting all the criteria save criterion V.
III. Three or fewer single-case experiments otherwise meeting all the criteria for well-established treatments.

Behavioral approaches are well represented on the well-established treatments and probably efficacious treatments, as shown in **Table 1** below.

Although the commitment to evidence-based practice (EBP) helped establish empirically based therapies in health care settings, there were inherent shortcomings in how EBPs were selected for inclusion on the list. The four major weaknesses of EBPs with respect to their applicability to clinical settings include the following: (1) Studies on the list were selected because of statistical significance not clinical significance (i.e., treatment outcomes might not be meaningful to patients and key stakeholders); (2) They were selected based on efficacy not effectiveness (a given therapy might be efficacious under ideal randomized control trial (RCT) conditions but not effective under routine care); (3) Selection criteria likely did not reflect more typical heterogeneous patient populations, as many patients with comorbid conditions are excluded from study participation (patients with a high degree of suicidality, e.g., are routinely excluded from depression studies); and there is (4) an obvious bias toward group design methodology and inferential statistics relative to single-case experimental designs and visual inspection methods akin to many behavioral approaches. Accordingly, although the deck has been stacked against behavior therapy, its participation on the EBPs list is quite impressive, nonetheless (*see* Evidence-Based Psychotherapy for an in-depth discussion on evidence-based psychotherapy).

Table 1 Well-established and probably efficacious treatments with a behavioral focus

Well-established treatments
Behavior therapy for depression: Jacobson et al. (1996); McLean and Hakstian (1979)
Behavioral modification for enuresis: Houts et al. (1994)
Behavior therapy for headache: Blanchard et al. (1980); Holroyd and Penzien (1990)
Parent training programs for children with oppositional behavior: Walter and Gilmore (1973); Wells and Egan (1988)
Behavioral marital therapy: Azrin et al. (1980a); Jacobson and Follette (1986)
Probably efficacious treatments
Exposure treatment for social phobia: Feske and Chambless (1995); Foa et al. (1991)
Systematic desensitization for abnormal phobia: Kirsch et al. (1983); Öst (1978)
Systematic desensitization for public speaking anxiety: Paul (1967); Woy and Efran (1972)
Systematic desensitization for social anxiety: Paul and Shannon (1966)
Behavior therapy for cocaine abuse: Higgins et al. (1993)
Community reinforcement approach for alcohol dependence: Azrin (1976); Hunt and Azrin (1973)
Cue exposure and adjunctive to inpatient treatment for alcohol dependence: Drummond and Glautier (1994)
Social skills training adjunctive to inpatient treatment of alcohol dependence: Eriksen et al. (1986)
Multicomponent operant-behavioral therapy for chronic pain: Turner and Clancy (1988); Turner et al. (1990)
Behavior modification of encopresis: O'Brien et al. (1986)
Exposure for simple phobia: Menzies and Clarke (1993)
Behavioral modification for sex offenders: Marshall et al. (1991)
Habit reversal and control techniques: Azrin et al. (1980b, c)
Social skills training for improving social adjustment for schizophrenic patients: Marder et al. (1996)

With that as background, let us turn to a few examples of behavior therapy as used with several clinical populations. Of course, these examples by no means represent all of the clinical applications of behavior therapy, considering its enormous breadth. The authors intentionally selected less familiar clinical contexts to many readers to demonstrate the flexibility of behavioral approaches.

Specific Examples of Behavioral Approaches to Clinical Disorders

Classical Conditioning and Anticipatory Nausea and Vomiting. Anticipatory nausea and vomiting (ANV) occurs by the fourth cycle in 25% of patients undergoing chemotherapy (Morrow and Roscoe, 1997; Morrow et al., 1998). ANV is best understood from a classical conditioning perspective (Bovbjerg, 2006). Neutral stimuli involving the clinic (e.g., sights, smells, sounds, etc.) come to elicit the cognitive restructuring (CR) (i.e., ANV) after a sufficient number of pairings with chemotherapy infusions (unconditioned stimulus (UCS)). As indicated, four pairings are sufficient to elicit ANV in about one-fourth of cancer patients. Interestingly, younger patients who report severe, frequent nausea, and/or vomiting after treatment are at elevated risk for developing ANV related to older individuals (Roscoe et al., 2011). The infusions act as the UCSs because they elicit nausea and vomiting (unconditioned response (UCR)) without prior conditioning.

Systematic desensitization using relaxation is most often used in psychological interventions in cancer care (Fawzy et al., 1995). Behavioral treatment for ANV involves blocking the association between potential CSs (conditioned stimuli) and the UCSs. Counterconditioning using systematic desensitization and relaxation strategies have proven effective in this regard (Morrow and Morrell, 1982; Lyles et al., 1982; Yoo et al., 2005). The relaxation response is believed to reciprocally inhibit and therefore block the transfer of function from UCSs to neutral stimuli (Wolpe, 1976).

Biopsychosocial Approach to Symptom Management in Schizophrenia. Schizophrenia, as is the case with any chronic condition, is best treated from a team-based biopsychosocial perspective (Bartels et al., 1998). The biopsychosocial model includes biological (e.g., genetic and neurological), psychological, and social variables in multimodal assessment and treatment. Antipsychotic medication is routinely the first line of treatment in order to manage the acute psychotic phase of the illness (Bradford et al., 2002; Marshall et al., 2005; Spencer et al.,

2001). Unfortunately, as many as 80% of patients with schizophrenia experience a relapse within 5 years of the initial episode (Álvarez Jiménez et al., 2011). Moreover, it has been estimated that over one-third of patients with schizophrenia experience medication-resistant symptoms (Garety et al., 2000). Accordingly, medication management and nonpharmacological interventions play key role in long-term symptom management. In a recent meta-analytic review of psychosocial programs for schizophrenia in younger adults, supported employment, cognitive therapy, cognitive behavioral therapy (CBT), and social skills training (including social problem-solving) all reported positive findings (Bustillo et al., 2001).

Supported employment entails on-the-job training (e.g., occupational therapy). Cognitive therapy and CBT approaches directly modify specific thoughts or beliefs that supposedly mediate maladaptive behavioral and emotional responding. The goals of CBT treatments are to reduce the extent to which one 'buys' delusional thoughts (Gould et al., 2001). Social skills training involves teaching patients effective interpersonal strategies within targeted social contexts (e.g., assertiveness skills) (Bartels et al., 1998).

Acceptance and commitment therapy (ACT) has also been used in managing psychotic symptoms and the preliminary outcomes have been favorable. Bach and Hayes (2002), e.g., reported lower symptom believability in their participants with psychotic disorders. Moreover, their study found a 50% reduction in the rate of psychiatric rehospitalization compared to treatment-as-usual over a 4-month follow-up period. Interested readers in applying ACT strategies to psychosis should consult the recent edited book titled, *Acceptance and Commitment Therapy and Mindfulness for Psychosis* (Morris et al., 2013; also, *see* Social Intervention in Psychiatric Disorders for a discussion on social interventions in psychiatric disorders).

Sleep Disorders in the Elderly. Sleep disorders are among the most prevalent and poorly addressed problems of aging (Phillips and Ancoli-Israel, 2001). Poor sleep quality increases risk for falls (Beck and Ailshire, 2013) and placement in an assisted or skilled nursing facility (Hartholt et al., 2011). With prevalence rates as high as 44% in older persons (National Sleep Foundation, 2003), it is estimated that fewer than 15% of chronic insomnia sufferers receive treatment (Mellinger and Balter, 1995). Sleep disorders generally fall into one of three categories: (1) insomnia (i.e., complaints of difficulty falling asleep, staying asleep, and nonrestorative sleep), (2) daytime sleepiness (e.g., narcolepsy), and (3) disorders of arousal that result in disruptive behaviors during sleep (e.g., breathing-related problems like sleep apnea) (Pagel and Parnes, 2001). Among these, insomnia, particularly staying asleep or sleep maintenance, is the most common problem in older persons with sleep disturbances (McCall, 2004). Problems with sleep maintenance can result from age-related physiological changes in the amount and pattern of various stages of sleep, psychological stressors, general medical conditions (e.g., congestive heart failure), psychiatric disorders (e.g., generalized anxiety disorder), and substance use (concurrent and recent discontinuation of use) (Prinz, 2004: p. 1739).

Nonpharmacological treatments of sleep disorders include sleep-hygiene, CBT, or a combination of the two (Martin et al., 2000). Meta-analyses reveal that these interventions are efficacious in the general population, with an average of 70–80% of participants demonstrating significant improvements in their sleep problems (e.g., restoring sleep latency close to normative levels) (Morin et al., 1994; Murtagh and Greenwood, 1995). Given the fact that pharmacologic interventions almost always entail significant side effects (particularly, hypnotic medications, such as benzodiazepines), and, thus, increase the risk of daytime impairment, whenever possible nonpharmacological treatments are always indicated first.

Stimulus control and sleep restriction involves reconditioning the bedroom environment to elicit sleep instead of arousal. This may entail directly altering the stimuli associated with sleep or the patient's response to these stimuli. Turning down the temperature, reducing noise (e.g., wearing earplugs), and dimming lights an hour before bed are several ways of directly modifying stimuli that promote sleep (or eliminate or reduce stimuli that disrupt sleep). Sleep restriction is designed to increase sleep efficiency. Bootzin et al. (1991) recommend the following as a means of establishing new routines with respect to sleep-associated stimuli: only go to bed when sleepy; use the bed only for sleep and sex; get up if it takes longer than 10 min to fall asleep and only return to bed when ready to fall asleep (e.g., after reading something nonstimulating, such as a technical manual); get up at the same time everyday, including weekends (this helps maintain circadian rhythms); and no napping during the day (as this disrupts circadian rhythms).

Relaxation is designed to lower arousal at bedtime and during nighttime awakenings. Diaphragmatic breathing (DB), self-hypnosis, and progressive muscle relaxation (PMR) are common examples. As indicated, CR is the core strategy in many CBTs. With respect to cognitive distortions, persons with insomnia tend to engage in all-or-nothing thinking (Lovato et al., 2013). Namely, they either perceive that they had a great night's sleep or a bad night's sleep nothing in between. Such black-or-white thinking makes it difficult appreciating slight improvements in sleep. Regarding misattributions, individuals with insomnia tend to blame all of their problems on their inability to achieve restful sleep. In other words, they catastrophize their sleep disturbances. Catastrophizing sleep problems can interfere with sleep initiation (*see* Sleep Disorders across the Life Span for further discussion on sleep disorders).

Anger and Coronary Heart Disease. Regarding long-term outcomes, in a recent meta-analysis examining 45 studies, Chida and Steptoe (2009) found that anger and hostility were associated with a 20% increased risk of incident coronary heart disease (CHD) in, otherwise, healthy individuals and a similar increased risk of poor prognosis in patients already diagnosed with CHD. Anger and hostility also increase acute risk for vascular events. For example, Mostofsky et al. (2014) reported that within 2 hours following an angry outburst, vulnerable individuals' risk of myocardial infarction (MI) or acute coronary syndrome, the risk of stroke, and risk of ventricular arrhythmia increased considerably relative to other times when they were not angry.

Ellis's (1962, 1994) rational emotive therapy "concentrates on people's current beliefs, attitudes and self-statements as contributing to or 'causing' and maintaining their emotional

and behavioral disturbances" (Ellis et al., 1988: pp. 1–2). What follows, therefore, is the notion that appropriate emotions are preceded by rational beliefs and inappropriate emotions like hostility are preceded by irrational beliefs (Ellis, 1971). Accordingly, irrational core beliefs ought to be disputed rationally. Cognitive disputations are attempts at changing erroneous beliefs through persuasion, didactic presentations, Socratic dialogue, vicarious experiences, among other approaches (Ellis, 1962, 1971, 1994; Walen et al., 1992).

Many CBT anger management programs involve some form of relaxation. The rationale for employing relaxation is largely based on reciprocal inhibition theory (Wolpe, 1958). Namely, arousal is inhibited after pairing relaxation with anger-provoking stimuli. The stress response and relaxation response are mutually exclusive (Benson, 1975). PMR, using Bernstein and Borkovec's (1973) standardized protocol, and DB are often recommended. PMR teaches patients how to discriminate between feelings of relaxation and arousal states, by having them notice physiological changes as they systematically tense and release various muscle groups in their bodies. By improving self-awareness, patients are better able to recognize arousal and, therefore, employ effective arousal-reducing coping strategies.

DB is also recommended, as it is relatively easy to learn and can be used in a variety of settings (see Hazelett-Stevens and Craske, 2003; for a review of breathing techniques). For example, patients can employ DB after changing lines for the second time at the department of motor vehicles (DMV).

A recent RCT of 427 with cardiovascular disease (CVD) indicated that at an average 94-month follow-up, the CBT group had a 41% lower rate of fatal and nonfatal first recurrent CVD events, 45% fewer recurrent acute MIs, and a nonsignificant 28% lower all-cause mortality (0.72 [0.40–1.30]; $P = 0.28$) (Gulliksson et al., 2011). Regarding general outcomes, several meta-analytic reviews of anger management programs (i.e., cognitive therapy, CBT, social skills training, and relaxation therapy – group and individual modes of delivery) have appeared in the literature (Beck and Fernandez, 1998; Edmondson and Conger, 1996; Tafrate, 1995; Vecchio and O'Leary, 2004). All reviews demonstrated medium to large effect sizes for some aspects of anger, while small for other aspects. Regarding explosive anger as often seen in patients with CHD, CBT, coupled with relaxation, appears to be the treatment of choice for anger expression problems (Edmondson and Conger, 1996; Vecchio and O'Leary, 2004).

Unresolved Issues: Behavior Therapy Has Drifted from Its Roots

Upon reviewing the list of empirically supported psychotherapies, one might be impressed with the significant contributions of behavior therapy, particularly when compared to the numerous alternative schools of therapy (e.g., psychodynamic, Gestalt, feminist, etc.). However, it is also somewhat striking that most of these contributions came from first-generation behavior therapy, with few exceptions (O'Donohue et al., 2001). Moreover, many of these contributions pertain to basic first-generation learning research around contingency management – not from the more recent advances in learning research such as matching, behavioral momentum, and response deprivation, to name only a few (see Pierce and Epling, 1999, for a discussion on these).

It might be useful and instructive to examine what has happened to CBT over the past 50 years; to take stock in what has been gained and, perhaps, even to see what might have been lost. It might be useful to start these with a more fulsome and historically relevant explication of the conceptual basis of early behavior therapy. In one of the first reviews of 'behavior therapy' published in the *Annual Review of Psychology*, Leonard Krasner (1971), an important first-generation behavior therapist, argued that behavior therapy had 15 major streams of development:

1. The concept of behaviorism (e.g., Skinner, 1974).
2. The research in instrumental (operant) conditioning of Thorndike (1931) and Skinner (1938).
3. The development of the technique of reciprocal inhibition, based on Holliman learning theory, as a 'treatment' procedure (Wolpe, 1958).
4. The experimental studies based on learning principles of a group of clinical investigators at Causley Hospital in London under the direction of H.J. Eysenck (*Experiments in Behavior Therapy*, 1964).
5. The application of conditioning and learning concepts to human behavior problems in the United States, from the 1920s to the 1950s, by such investigators as John B. Watson, Mary Cover Jones, and E. Lain Phillips.
6. The interpretation of psychoanalysis in terms of learning theory (e.g., Dollard and Miller, 1950), enhancing learning theory as a respectable basis for clinical work.
7. The conditioning paradigm of classical conditioning derived from Ivan Pavlov as the basis for explaining and changing both normal and deviant behavior.
8. Theoretical concepts and research studies of social role learning and interactions in social psychology and sociology (e.g., George Humans, George H. Mead, Alcott Parsons, and Theodore Sabin).
9. Research in developmental and child psychology emphasizing various learning and modeling (e.g., Albert Bandura, Sidney Bijou, and John Dollard).
10. Social influence studies of demand characteristics, experimenter bias, hypnosis, and placebo.
11. An environmentally based social learning model as an alternative to the 'disease' model of human behavior (Bandura, *Principles of Behavior Modification*, 1969, Krasner and Ullmann, 1965).
12. Dissatisfaction with psychotherapy and the psychoanalytic model, as evidenced by several strong critiques (e.g., Eysenck, 1952).
13. The development of the idea of the clinical psychologist within the scientist–practitioner model (also known as, 'clinician–scientist').
14. A movement within psychiatry away from the orthodox focus of internal dynamics and pathology, toward concepts of human interaction and environmental influence (e.g., Adolph Meyer and Harry Stack Sullivan).
15. A utopian emphasis on the planning of social environments to elicit and maintain the best of human behavior (e.g., Skinner's *Walden Two*, 1948).

What seems to have changed over the past 50 years? Here is a partial list:

1. *Less alliance and interest in behaviorism.* It appears now that CBT is less 'deep' or, to put it more positively, simply oriented to a form of science in which randomly controlled trials are used to evaluate the effectiveness of certain techniques or packages of techniques. Skinner (1972), e.g., attempted to develop an integrated scientific and theoretical framework in which radical behaviorism served as a foundation for his experimental analysis of behavior, which in turn served as a foundation for applied behavior analysis. Modern cognitive behaviorists seem less concerned with these kinds of conceptual foundations and perhaps see nothing unusual in finding substitutes for these in such areas as Buddhism, feminism, or postmodern theories. This is somewhat of a change in the sociology and philosophy of the profession overall.
2. *More acceptance of the* 'medical model.' Early behaviorists argued against the reification of disease. They fought against the view that abnormality resulted from different processes than normality. They saw that what separates normal from abnormal in psychology was often a value judgment. They even objected to the word 'patient' and wanted to use terms like 'client' to differentiate what clinical psychologists were doing from what medical professionals such as psychiatrists were doing. However, for a variety of reasons, perhaps partly due to the power of the medical establishment, perhaps partly due to the assumptions of grant funding, contemporary behaviorists seem less concerned with the conceptual implications and problems of the medical model.
3. *Less interest in reciprocal inhibition and systematic desensitization.* Wolpe's work was quite influential in the late 1950s and early 1960s. However, it is less important now. Little research is being done on systematic desensitization or concepts like reciprocal inhibition. It is interesting to note that even in its origins in behavior therapy, it had several different subschools – there were Skinnerians emphasizing operant analysis and Wolpeans interested in Hullian learning constructs and reciprocal inhibition.
4. *Less emphasis on learning principles.* Principles are being derived from an eclectic mix of sources: Buddhism, Hegelian dialectical philosophies, postmodernism, semantics, Greek virtue ethics (positive psychology), etc. While certainly the pragmatic view of use-anything-and-everything-that-might-work has some merit, some intellectual coherence might be lost. Learning principles as powerful principles from the psychological laboratory had been evaluated by scientific means and were partly chosen because of their record of powerful effects – a very good approach to clinical problems. It is not so clear if these more contemporary sources of influence have the same sort of credentials.
5. *More emphasis on package treatments where process variables are less clear.* Early researchers often explicitly investigated the role of an experimental principle for modifying a clinical problem. Titles of journal articles were often along the lines of, "The use of contingency management to reduce tantruming" or "The use of shaping to increase vocalizations in an electively mute woman." Modern titles differ in two ways: (1) These more often do not refer to criterion behavior but rather to some other abstraction (e.g., acceptance or self-efficacy or to a diagnostic and statistical manual of mental disorders (DSM) diagnostic category like major depression); and (2) the intervention is less a clear process variable and much more a package: e.g., dialectical behavior therapy (DBT) or an anger management package consisting of a number of different elements. While certainly some of this may be derived from the hope that these packages will result in increased effectiveness, the process and mechanisms of change are less clear. At the minimum, this necessitates further research using dismantling designs to try to understand the mechanisms of change in these packages (*see* Psychotherapy Process Research for a further discussion on psychotherapy process research.)
6. *Less concern with psychoanalysis as a rival.* Although psychoanalysis has not completely died, it is not longer a strong competitor. The competitors for CBT now are much more likely to be psychotropic interventions, or vaguely defined supportive interventions (*see* Prophylaxis in Psychiatry for a discussion on medications used in psychiatry).
7. *More microcommunities (Kuhn) of behavior therapists.* Behavior therapy was never monolithic but has become increasingly divided into microcommunities. Sometimes these divisions occur along theoretical lines (the Skinnerians vs the cognitivists); sometimes along interest in a particular therapy approach (ACT vs DBT vs traditional CBT), or sometimes along a particular problem interest (those interested in depression vs those interested in Oppositional Defiant Disorder). But, increasingly, two cognitive behavior therapists, if they differ on these dimensions, may have little in common and there is seldom if any cross-pollination of ideas.
8. *Less utopianism.* Early behavior therapists, probably both due to Skinner's utopian interests and influenced by the Zeitgeist of the 1960s, thought 'big' – they often wanted to solve large societal problems such as pollution, the threat of nuclear war, or problems in the educational system. More contemporary behavior therapists think in terms of coming up with more effective treatments for a particular DSM diagnosis.
9. *Less concern with the possible tensions between cognitive and behavior therapy.* This was for many years a relatively 'hot' debate. There seems to have been a lot of quelling of the heat around this issue.
10. *A restricted scholarly scope.* One can see from Krasner's analysis that first-generation behavior therapists were synthesizing a lot of information from a number of scholarly domains: from learning research; from social psychology; from radical psychology and its critiques of the medical model, and the construct of mental illness; from philosophy of mind; and from a number of other disciplines. Contemporary behavior therapy seems less integrative, although certainly there is some interest in certain influences such as Buddhism.
11. *The emergence of third wave behavior therapies, particularly mindfulness.* The contemporary interest in mindfulness would probably come as a surprise to first-generation

behavior therapists. Nonmentalistic constructs were thought of as essential to this group, generally seeing that this was consistent with their philosophy of science – i.e., some form of behaviorism.

12. A loss of some of the uniqueness of behavior therapy methodological preference: e.g., the increased use of questionnaires instead of measuring criterion behaviors. Behavior therapy research in the first generation was somewhat unique – certainly the single-subject designs of proponents of Skinnerian behaviorism were. But their general intellectual commitments also wanted them to deal with criterion behavior directly – e.g., they wanted to count cigarettes and not look at a questionnaire purportedly measuring 'self-efficacy to stop smoking' or 'avoidance.' However, it also might be argued that the research methods used by cognitive behavior therapists have become more 'sophisticated.' There certainly has been increased sophistication in methodologies and data analysis involving rather elaborate statistical applications. Arguably, increased complexity in statistical techniques makes interpretation of outcomes more obscure. Few consumers of research and researchers for that matter fully understand the complexities of the multivariate analytic technique of structural equation modeling. In fact, more often than not, statisticians and quantitative psychologists are recruited on large-scale studies, as principal and coinvestigators lack the necessary skill set to run those analyses appropriately themselves. Accordingly, if the investigators cannot understand the analytic strategies, then how can one assume that these studies are within the grasp of consumers of that research who are likely less familiar with the content area?
13. *The influence of health care insurance companies has increased.* Insofar as the behavior of research participants and patients can be influenced by prevailing contingencies of reinforcement, so can the behavior of clinicians and researchers. Naturally, financial contingencies play a significant role on the behavior of researchers and practitioners. Federal and private grant agencies almost invariably fund projects based on DSM diagnostic categories (e.g., NIH RO1 for depression). Similarly, clinicians are reimbursed by insurance companies using international classification of diseases (ICD) and DSM diagnoses. In fact, there are special diagnostic categories, which garner higher reimbursement rates – so-called risk-adjusted diagnoses (e.g., a diagnosis of major depression versus depression not otherwise specified (NOS) garners an additional $3200 per patient annually), which, ultimately, shape the diagnostic practices of clinicians. Coding specialists and practice-review specialists employed by health care agencies also exert influence on what is actually done in session (*see* Psychiatric Care, Economics of for a discussion on the economics of behavioral health care).

Conclusions

CBT has a complex history with evolving intellectual allegiances and interests. Complicating matters further, being inextricably tied to the health care environment, behavior therapy has evolved in keeping with the same market forces that have greatly influenced how medicine and other therapeutic orientations are practiced. Given pragmatic aims and a strong commitment to empiricism, behavior therapists are especially well posed to meet the complexity and demands of the ever-changing market as health care costs continue to rise exponentially while national dollars allotted to health care dwindle. Upon reviewing the list of empirically supported psychotherapies, it is striking just how many significant contributions of behavior therapy appear on the list. Moreover, it is equally as striking that most of these contributions came from first-generation behavior therapy, with few exceptions (O'Donohue et al., 2001). Behavior therapy is, ultimately, a growing and dynamic enterprise that should understand its roots to better appreciate what is lost and what is gained as it evolves.

Abstract

Behavior therapy and cognitive therapy describe ways to help patients change their responses in order to reduce distress and other problems. The problems include anxiety, social skills and depressive disorders, couple difficulties, learning disabilities, and aspects of psychoses. Guidance may be given face to face, by phone, book, or online. Attaining enough enduring improvement may need days, weeks, or months of help depending on the duration, severity, and complexity of the problem. Added antidepressant medication can be beneficial, if mood is low.

Behavior therapy refers to a range of methods to change a person's responses to specific situations. Altering those responses often alleviates distress and psychiatric problems. An early behavioral treatment of phobic disorders was systematic desensitization, which teaches patients to relax and then imagine their anxiety-evoking scenes repeatedly. Systematic desensitization is a form of graded exposure. Later, patients were asked to gradually face their feared situations until the fear began to subside, gradually increasing the fear intensity of those situations up their hierarchy. This is now the treatment of choice for phobic, obsessive-compulsive, and other anxiety disorders.

Other behavioral methods teach social skills to sufferers with problems such as social skills deficits, marital disharmony, and sexual dysfunction. Further behavioral methods reward desired behaviors and ignore or suppress undesirable ones – such methods are used most often in chronically institutionalized patients.

Behavior therapy is commonly used together with cognitive therapy, which helps patients to examine their thinking patterns and challenge unhelpful ways of thinking. Behavior therapy is also frequently combined with antidepressant drugs if mood is low.

A useful definition of behavior therapy is that of Meyer and Chesser (1970): Behavior therapy aims to modify current symptoms and focuses attention on their behavioral manifestations in terms of observable responses. The techniques used are based on a variety of learning principles. Although behavior therapists adopt a developmental approach to the genesis of symptoms, they do not think it is always necessary to unravel their origin and subsequent development.

In psychiatric practice, behavior therapy has improved anxiety and obsessive-compulsive disorders, habit disorders, and challenging or antisocial behaviors. Cognitive therapy that helps people examine their thinking patterns and alter maladaptive thoughts can often be used effectively together with behavior therapy. Combined cognitive behavior therapy improved depression, panic, generalized anxiety, posttraumatic stress, and other psychiatric conditions.

History of Behavior Therapy

Past historical documents described treatments of children and adults with techniques, which are now called behavior therapy, though anxiety disorders and other neuroses have often been treated by psychoanalytic psychotherapy since the early twentieth century. The latter assumes that psychiatric disorders are due to unconscious conflicts, which can take years of psychoanalysis to resolve. An early challenge to this belief was the work of Watson and Rayner with Little Albert (Watson and Rayner, 1920). Little Albert was a young boy who had shown no fear of animals. Watson and Rayner placed him in a room with a white rat. Whenever Albert approached the rat, the researchers made a loud aversive noise. Through such classical conditioning Albert quickly developed a fear of white rats, which generalized within hours to other furry objects and animals.

A few years later, Jones (1924) tried reward techniques in children with preexisting phobias. She used food with hungry children and brought the feared object toward the child as it ate. Any fear response caused her to move the frightening object further away until the child started eating again. This was repeated until the child was happy even when close to the feared object.

Despite such early examples of the use of behavioral principles, behavior therapy was not defined as a discipline until the 1950s when Joseph Wolpe popularized systematic desensitization for phobic disorder. Systematic desensitization assumes that an individual or group cannot simultaneously feel relaxed and also experience anxiety. Fear of a phobic stimulus can be reduced and eventually extinguished by learning to relax while imagining a series of increasingly frightening scenes. A hierarchy of increasingly fear-evoking stimuli was obtained from the patient and initially, after she/he had induced relaxation, they were asked to imagine a slightly frightening situation. Once this was tolerated, the patient was asked to move a step at a time to imagine increasingly threatening images. If the patient became anxious, the therapist asked the patient to relax again and then imagine

a less-frightening stimulus (Wolpe, 1958). Since that time there have been many studies of systematic desensitization. For example, Gelder et al. (1967) compared systematic desensitization with individual psychotherapy and with group psychotherapy in patients with phobic disorders. Systematic desensitization was consistently better than individual or group psychotherapy.

Although systematic desensitization is effective for specific phobic disorders, it involves a long laborious process of very gradual exposure. Quicker benefit was obtained with real-life exposure methods, one of which was called flooding (Stampfl and Levis, 1967). Real-life exposure involves asking the patient to face the feared stimulus without using relaxation or distraction. Even though this causes anxiety, if the patient remains in contact with the stimulus for sufficiently long (up to 1 h), then the anxiety does gradually reduce. Such exposure too is done up a hierarchy, starting with a situation that causes moderate anxiety before progressing to situations which the patient, unlike most other people, finds very frightening. The hierarchy is less structured than in systematic desensitization and is usually effective after only a total of a few hours in all of exposure.

Real-life exposure methods were pioneered with specific phobias (Watson and Marks, 1971). Specific phobics were treated with rapid exposure in real life with great success. Fears by some therapists that anxious patients would be made worse and other symptoms would appear proved to be unfounded. Exposure treatment was then tried for agoraphobia and shown to be effective (Mathews et al., 1976). From 1970 to 1980, exposure treatments for agoraphobia were refined and crucial treatment factors were isolated. For example, longer duration of exposure was better for improving agoraphobia (Stern and Marks, 1973). Real-life exposure was more effective than even very rapid imaginal exposure (Emmelkamp and Wessels, 1975).

Over the next few years, refinement of psychological treatment for agoraphobia continued. It was thought that if treatment could be done in groups, it would be more cost effective. Hand et al. (1974) compared 'structured' with 'unstructured' groups, and found progress was greater in the structured group. Only the structured group continued to improve after treatment and three month follow-up. Group exposure required less professional time and so was an advance in treatment. However, in practice it is often hard to get a group of similar phobic patients together at the same time, and progress of the group as a whole is linked to the speed of progress of its slowest member.

More recent work in the treatment of anxiety disorders has been in the development of self-exposure where the patient is given detailed instructions about how to perform exposure treatment but the therapist is not present during the exposure therapy. Marks et al. (1983) showed that brief therapist-aided exposure was a useful adjunct to self-exposure homework instructions, and even self-exposure homework instruction alone, unaccompanied by a therapist, is a potent treatment for agoraphobia. Experience to date supports the use of this approach, although involvement of family members as cotherapists can be beneficial.

The treatment of obsessive-compulsive disorder was developed at the same time as that for agoraphobia. Marks et al. (1975) reported the results over 2 years of 20 patients with chronic compulsive rituals treated by real-life exposure. This treatment reduced the rituals as it did agoraphobia. The only difference between the real-life exposure used in obsessive-compulsive disorder and in phobic disorder is that with OCD, the patient is also asked not to perform the anxiety-reducing rituals, which are salient in this disorder. These anxiety-reducing rituals would otherwise interfere with the natural habituation to anxiety, which occurs with prolonged exposure. In patients with rituals, the therapist often initially modeled exposure and ritual prevention.

A similar treatment for obsessive-compulsive rituals had been described in 1903 by the French psychiatrist, Janet. He wrote: "The person who assists in the performance of these actions, has a very complicated part to play. He must aid in the performance of the action without actually doing it himself, although the latter would be very much easier; and he must do his utmost to conceal his own contribution to the action, for it is essential that the patient should feel he does the action himself and does it unaided. The guide has chosen the action, has overcome the patient's hesitations, and has taken the responsibility … by continual repetition to perform the action; by words of encouragement at every sign of success however insignificant, for encouragement will make the patient realize these little successes, and will stimulate him with the hope aroused by glimpses of greater successes in the future."

The principles outlined by Pierre Janet were refined in later studies (Levy and Meyer, 1971; Rachman et al., 1971). Now a truly effective therapy can be offered to most patients with compulsive rituals.

As well as being a treatment for phobic, obsessive-compulsive, and other anxiety disorders, behavior therapy has also been applied to other complaints as varied as schizophrenia and marital/sexual dysfunction. The use of behavior therapy in schizophrenia and learning disability started when Ayllon and Azrin (1968) used operant reinforcement principles to help patients with chronic schizophrenia. Nowadays, behavior therapy is used to counteract secondary handicaps of schizophrenia and to aid patients discharged from hospital to the community. In 1970, the pioneering work of Masters and Johnson (1966, 1970) led to a range of behavioral techniques for sexual dysfunction.

There are many other conditions where behavior therapy has been effective but these cannot be detailed in this short article. There is a trend now for behavior therapy to be used for an increasing range of disorders, and much progress has been made since the first tentative exposure techniques.

Modern Behavior Therapy

This section has three main parts. The first deals with the current use and application of exposure methods of treatment, which are used mostly for anxiety disorders. The second examines methods to teach new skills where these have not been learned, e.g., forms of social skills training for sexual dysfunction, marital therapy, and problem solving. Third, there will be a description of the use of reinforcement techniques for learning disability, chronic patients, and in child psychiatry.

Exposure Treatments

Exposure treatment is effective in two-thirds of agoraphobics (Mathews et al., 1981) and up to 85% of obsessive-compulsives (Foa and Goldstein, 1978; Rachman et al., 1979), and is highly effective (Marks, 1981) in specific and social phobics.

There is often fear of using exposure treatment outside specialist centers. This seems to stem from erroneous views about its applicability, its success rates, the time commitment required by the therapist, and fear of the unknown. In fact, graded exposure is a quick and cost-efficient treatment, which can be easily applied in many general practice and hospital settings (Marks, 1981, 1986; Stern and Drummond, 1991). Basic training can easily be obtained by reading about clinical techniques (Hawton et al., 1989; Stern and Drummond, 1991), reading the self-help Chapter-12 section of Living With Fear (Marks, 2001), and by obtaining supervision from a trained behavioral psychotherapist (Drummond, 2014).

The most effective exposure is:

1. Longer rather than shorter in duration (Stern and Marks, 1973).
2. Done in real life rather than in fantasy (Emmelkamp and Wessels, 1975).
3. Practiced regularly with self-exposure homework tasks (McDonald et al., 1978).

A past concern about exposure treatment was the mistaken idea that it requires considerable professional input to accompany an anxious patient into fear-evoking situations. It has been shown that instruction in self-exposure techniques is all that is needed for many patients with phobic anxiety and obsessive-compulsive disorder (Ghosh et al., 1988; Marks et al., 1988). The efficacy of self-exposure led to the development of self-help manuals. Some patients can complete self-treatment successfully without professional guidance. In fact, many sufferers treat themselves with online guidance from programs such as FearFighter, OCFighter, and Cope. Other people need to be seen initially for education about anxiety and its treatment and for help in devising treatment targets. Subsequent sessions are used to monitor progress, give encouragement, and advise on any difficulties, which may arise (Ghosh et al., 1988).

Exposure is the cornerstone of treatment of obsessive-compulsive disorder when it is combined with ritual prevention – patients are encouraged to refrain from performing rituals and compulsions. Rituals are overt behaviors or internal thought patterns, which are used to counteract obsessive fears. Rituals can usually be prevented or reduced substantially by showing the patient how they interfere with exposure. In exposure therapy, the aim is to produce prolonged periods of contact with the feared situation until the ensuing anxiety reduces (habituation). Compulsions (rituals) immediately reduce the anxiety – this serves to reinforce the ritual. However, the reduction in anxiety produced by a ritual tends to be small and temporary. In effect, rituals prevent therapeutic exposure and instead further increase the tendency to ritualize.

Exposure methods have also been used to treat other anxiety disorders to good effect, including post-traumatic stress disorder (Keane et al., 1989; Foa et al., 1991) and hypochondriasis (Warwick et al., 1996).

Teaching New Skills

Some people lack appropriate skills to meet certain challenges of the environment in which they find themselves. This is, of course, true to some extent for most of us. However, with some people, specific training can resolve a crisis and remove psychological distress.

Skills training begins with the therapist establishing in detail with the patient what skills are at fault and what this leads to. This analysis is followed by sensitive discussion about how the skills could be improved. Frequently the therapist will then model the skill to be achieved. With a complex skill or where the patient has a very low level of skill in the area, the skill may have to be broken down into a series of stages, which are presented one at a time. The therapist then asks the patient to rehearse the new skill during the session and gives feedback. It is important that this feedback is encouraging, highlights positive aspects of the performance, and suggests how it might be improved. In some cases, video or audiotape recordings can also be used to give the patient additional feedback about progress. The patient is then asked to practice the skill. This continues until the patient is able to use the new skill in everyday life.

These techniques are frequently used in social skills training, which are often applied to groups. In couple therapy, the methods can be used in behavioral exchange therapy to encourage the couple to do positive things for each other using a 'give to get' principle. The methods may also be used to encourage positive communication between couples. Similar skills are also used in sex therapy, which is based partly on the exposure principle in anxious individuals and also aims to improve basic sexual knowledge and skill. In the case of sex therapy, the therapist does not demonstrate the skill but describes it using diagrams and the couple is asked to practice at home.

Problem-solving techniques can be used as an adjunct to other therapies for many patients. The patient is taught how to describe a problem and to weigh up the pros and cons of a decision. A discussion then follows of what an appropriate response might be to yield the best result. This is followed by rehearsal of the required skills.

Studies of sexual skills training showed it to be an effective treatment for a range of sexual problems (Masters and Johnson, 1970; Bancroft, 1983). Social skills training has had favorable results for people with social skills problems (e.g., Stravynski et al., 1982).

Operant Techniques for Chronic Problems

In patients with chronic behavior problems, operant conditioning methods are often used. Operant methods employ rewards that the patient values. The Premack (1959) principle addresses this by using a high-frequency preferred activity to reinforce a lower frequency, nonpreferred activity. As an example, if a teenage girl spends most of her time surfing the net, this high-frequency preferred activity could be used to reinforce the lower frequency nonpreferred activity of tidying her bedroom.

Use of this approach to reduce undesired behaviors and increase socially acceptable behavior has grown in recent years

since the closure of many older psychiatric institutions and a move toward community care. Discharge to the community or admission to a psychiatric unit of a district general hospital often means that bizarre or socially unacceptable behavior is tolerated less well than in older institutions, which were often segregated from the rest of society.

By far the most commonly used form of reinforcement is positive – reward. Negative reinforcement or even punishment is hardly ever used and usually only in dangerous or life-threatening situations due to the obvious ethical dilemmas presented by such methods. Ethical problems may also arise with positive reinforcement, especially if essential items such as food are used as rewards and the patient has not earned a meal that day.

Reinforcers Which Increase Desirable Behaviors

Positive Reinforcers

1. Social approval, e.g., therapist's approval of a phobic patient who has completed an exposure task.
2. Higher frequency preferred activities.
3. Feedback reinforcement, e.g., in a social skills group.
4. Food reinforcers.
5. Tokens awarded for certain behaviors, which the patient can exchange for a range of rewards.

Negative Reinforcers

This is the removal of an aversive event after a specific required response is obtained. It poses ethical problems and so is rarely used except with a consenting adult. For example, a man with an illegal sexual preference can be trained to imagine aversive scenes following arousing deviant images. He is also taught to gain relief from these aversive experiences by switching to neutral thoughts.

Reinforcers Which Reduce Undesirable Behaviors

Punishment

1. Time out, i.e., removal of the patient from a rewarding environment for up to 3 min.
2. Overcorrection – e.g., if someone smashes his cup to the floor, he is asked to not only clear up the mess but then to also wash the entire ward floor.
3. Positive punishment – e.g., if a child puts its finger toward an electric socket and receives a sharp slap on the hand.

Response Cost

1. Penalty involving some time and effort in response to certain behaviors.
2. A positive reinforcer is removed if certain undesired activities are indulged in.

The Future of Behavior Therapy

Although behavior therapy in the form of exposure remains the psychological treatment of choice for phobic, obsessive-compulsive, and other disorders, it is often combined with cognitive techniques. Many recent studies in conditions as varied as schizophrenia (Tarrier et al., 1993; Kingdon et al., 1994) and hypochondriasis (Warwick et al., 1996) describe cognitive behavior therapy. Further work is needed to identify the specific therapeutic factors in these treatment packages.

The treatment of anxiety disorders has developed rapidly since the 1980s. Anxiety can be treated using behavioral or drug treatments, and sometimes both, e.g., antidepressants as an adjunct when mood is low.

Overall, behavior therapy is of known efficacy for many psychiatric symptoms. It can be combined with cognitive techniques to improve the patient's compliance or to improve the outcome. Antidepressant drugs may also be used together with behavior and cognitive therapy. More research is needed into which ingredients of treatment packages are the most beneficial for patients.

Behavior Therapy: The Second and Third Waves

Abstract

First-generation or first-wave behavior therapy developed out of dissatisfaction with psychoanalysis. Though it showed much promise in treating rather intractable conditions that eluded psychoanalysts at the time, it, too, was not above criticism – which gave rise to the second wave of behavior therapy. Cognitive therapy and cognitive behavior therapy (CBT) emerged out of the second wave. Cognitive therapy and CBT were successful in treating numerous complex psychiatric disorders including recurrent depression, posttraumatic stress disorder, panic disorder, and obsessive-compulsive disorder.

The third wave supposedly developed out of dissatisfaction with the second wave of behavior therapy. Acceptance and commitment therapy, dialectical behavior therapy, functional analytic psychotherapy, and behavioral activation are several of the most influential third-wave therapies. The third wave introduced a number of new concepts and terms into the behavioral canon including, metacognition, cognitive fusion, emotional regulation, acceptance, mindfulness, and dialectics. As will be taken up later, the third wave might have been oversold and may not actually fit within the general properties of an evidence-based orientation of behavior therapy.

First-generation or first-wave behavior therapy grew, in part, out of dissatisfaction with psychoanalysis in treating various intractable, chronic psychiatric conditions. Although it showed promise in treating a number of these, practitioners eventually became dissatisfied with the first wave of behavior therapy – particularly when those earlier technologies were applied to clients with more complex behavioral repertoires. Perceived shortcomings in treating certain patient populations gave rise to the second wave of behavior therapy. The second wave introduced concepts and terms from the basic laboratory of cognitive psychology and from folk notions regarding rationality and positive thinking, emphasizing the role of cognitive processes in clinical disorders. Cognitive therapy (CT; Beck, 1976; Beck et al., 1979) and cognitive behavior therapy (CBT; Ellis, 1961, 1962, 1975; Meichenbaum, 1977) were born out of this movement and were also successful in treating a variety of complex psychiatric disorders including recurrent depression, posttraumatic stress disorder (PTSD), panic disorder, and obsessive-compulsive disorder (OCD) (*see* Concepts and Methods of Cognitive Therapies for an in-depth discussion on various concepts and methods of CTs and CBTs).

The third wave supposedly developed out of dissatisfaction with second-wave cognitive approaches. The third wave is composed largely of acceptance and commitment therapy (ACT), dialectical behavior therapy (DBT), functional analytic psychotherapy (FAP), and behavioral activation (BA), among others (Hayes et al., 2006). Interestingly, as a side note, Marsha Linehan – the founder of DBT – reportedly, does not consider DBT a third-wave therapy. Rather, in her view, DBT is a "form of classic CBT that includes acceptance strategies" (David and Hofmann, 2013: p. 116). Accordingly, she would see DBT as a member of the second wave. The third wave introduced a number of new concepts and terms to the behavioral canon including, though not limited to, metacognition, cognitive fusion, emotional regulation, acceptance, mindfulness, dialectics, and commitment to meaning (Kahl et al., 2012).

The purpose of this article is to provide a general overview of second- and third-wave therapies. Readers should note that these schools of thought are nearly impossible (if not impossible) to neatly summarize using a few simple properties that pertain to each and every member. Behavior therapies, rather, share what Wittgenstein (1952) referred to as a 'family resemblance.' A family resemblance shares common, essential properties that play a central role in a complex web of belief (Quine and Ullian, 1970). Wittgenstein (1958) elucidated this concept using the notion of 'game' as a case in point:

> Compare chess with noughts and crosses. Or is there always winning and losing, or competition between players? Think of patience. In ball games there is winning and losing; but when a child throws his ball at the wall and catches it again, this feature has disappeared. Look at the parts played by skill and luck; and at the difference between skill in chess and skill in tennis… I can think of no better expression to characterize these similarities than "family resemblances" (PI § 66–67)

Accordingly, insofar as one can find family resemblances in games, commonalities can be readily seen emerging and disappearing in second- and third-wave therapies.

Second-Wave Behavior Therapy

There was a watershed event in the history of psychology during the late 1940 and the 1950s, where psychologists took one of two major paths: there were those who remained faithful to the behavioral tradition and there were those who broke ties with that tradition, pursuing cognitive psychology (Baars, 1986; Hergenhahn, 1997). Two important dates that were attributed to this breach of the behavioral tradition were 1948 and 1956 (Leahey, 1992). The former year marked the Hixon Symposium on Cerebral Mechanisms in Behavior (Gardner, 1985), and the latter marked the Symposium on Information Theory at the Massachusetts Institute of Technology (Baars, 1986). Basic research in cognitive psychology

had a significant influence on behavior therapy throughout the 1960s, even until the present day, in cognitive neuroscience. Major cognitive and cognitive behavioral approaches of the second generation of behavior therapists are Beck's (1976) CT, Ellis's rational emotive therapy (1962; though it has since been renamed rational emotive behavior therapy), Meichenbaum's (1977) self-instructional training, and, more recently, metacognitive therapy (Wells and Matthews, 1994).

CBT employs both cognitive and behavioral techniques in designing treatments. There are several assumptions underlying all CBT interventions. First, thoughts or beliefs, emotions, and behavior are interrelated. Behavior therefore affects thoughts and feelings and thoughts and feelings in turn affect behavior. Thoughts, feelings, and behavior are therefore inexplicably tied to one another. Second, changing 'automatic thoughts,' core beliefs, and/or behavior affects mood. Identifying and modifying negative or dysfunctional beliefs and/or engaging in more adaptive behavior, therefore, can eventuate in improvement in a person's mood. Three, all CBT interventions employ similar techniques built around one core strategy, cognitive restructuring, to which the authors now turn (Edmondson and Conger, 1996).

Cognitive restructuring is the core strategy in CT and most CBTs (Mahoney, 1977). It is a treatment technique that is designed to directly modify specific thoughts or beliefs that are believed to mediate maladaptive behavioral and emotional responding (Foa and Rothbaum, 1998). The patient, for example, might be assisted in identifying the so-called distorted schemas and related automatic thoughts that moderate anxiety responses (e.g., 'I'm inherently a bad person'). The therapist might assist the patient in replacing those distorted messages with positive, more realistic cognitive beliefs and messages (e.g., 'I sometimes behave badly in specific circumstances, but I also behave well in other situations').

There has been some dissatisfaction within CT regarding the bases of understanding of the general role of cognition in normal and abnormal human behavior. Ellis and Beck have generally not been influenced by the literature in basic experimental psychology. Instead, they have relied on folk notions of rationality (e.g., do not overgeneralize) and informal notions of what constitutes harmful irrational beliefs (e.g., Ellis' assertion that "Everyone must like me or else I am not a good person"). Others such as Dimidjian and Hollon (2010), Hollon et al. (1993), and McFall (1991, 1996) have suggested that this is a poor basis for clinical theories and strategies. They, in contrast, argue that CT ought to be based on experimental cognitive science – in much the same way that behavior therapy is based on the findings of learning and conditioning in the experimental laboratory.

Third-Wave Behavior Therapy

The behavioral perspective on cognitive phenomena has engendered a relatively new psychological therapy called acceptance and commitment therapy, which holds promise treating individuals with intractable conditions like chronic pain, substance abuse, and chronic suicidality (Hayes et al., 1999). Readers should note, however, that the term *promise* is used here, as ACT has yet to show superiority over extant approaches like CBT (see recent meta-analyses: Levin and Hayes, 2009; Powers et al., 2009; Ruiz, 2010, 2012). Moreover, although ACT has made some lists of empirically supported therapies, often these lists are constructed by ardent ACT supporters. Some critics, in contrast, conclude that "no third wave therapy fulfills the criteria for empirically supported treatments" (Öst, 2008: p. 315). Specifically, "The review of the RCTs for ACT shows that there is no study that is methodologically good enough and also fulfills the first of the EST criteria" (p. 313), i.e., "At least *two* good between-group design experiments must demonstrate efficacy in one or more of the following ways … superiority to pill or psychotherapy control, or to other treatment … equivalence to already established treatment with adequate sample sizes" (Chambless et al., 1998).

A third-wave perspective on cognitive phenomena as shown in ACT places a premium on how language (verbal behavior) interrelates with nonverbal behavior in a bi-directional manner (Hayes and Gifford, 1997). This mechanism is called rule-governed behavior (Hayes, 1989). Rules are special classes of verbal behavior (Baum, 1994), defined in functional terms, according to their involvement as a special class of discriminative stimuli (Catania et al., 1989: p. 120). Rules thus serve as contingency-specifying stimuli (Pierce and Epling, 1999). That is to say, rules describe what behaviors, under what conditions, will likely eventuate in positive reinforcement or punishment. For example, the rule, always showing up to work on time and pleasing one's boss will likely result in further paychecks. In contrast, the rule, always arriving late to work, and making clients wait will likely eventuate in termination.

ACT is a principles-driven treatment designed to promote behavior and thinking patterns that are more flexible and adaptive as individuals strive to keep their commitments and pursue their values (Wilson and Roberts, 2002). ACT modifies psychological functioning and behavior by altering the social and verbal contexts that are believed to link thoughts and feelings to overt actions. According to proponents of ACT, psychological inflexibility results from cognitive fusion or "excessive or improper regulation of behavior by verbal processes" (Hayes et al., 2006: p. 6). Cognitive fusion arises when words like 'I' and 'me' merge with statements like ('I' + 'am no good' or 'I' + 'do not deserve to live').

Cognitive fusion is oftentimes seamless, thus creating the illusion that no such verbal processes actually transpired (Hayes, 2004; i.e., the 'I' + what followed has always been the case). Accordingly, people are inclined to accept those self-evaluative statements prima facie, as if they were statements of facts or literal truths, not simply a thought or interpretation about how the world is arranged (Hayes and Wilson, 1994). ACT uses the terms literalization and the neologism 'deliteralization' to get at this process (Hayes et al., 1999). Experiential avoidance is more likely following cognitive fusion (Hayes et al., 1999). Individuals use drugs of abuse, increasingly isolate themselves, and, worse still, take their own lives to avoid contact with extremely painful thoughts and emotions that have fused with an individual's self-concept or sense of self-worth (Chiles and Strosahl, 2005).

Psychological flexibility – the opposite of psychological inflexibility – is promoted through six core processes of change, including acceptance, defusion, mindfulness, self as context, values, and committed action (see Strosahl et al., 2004; for an in-depth discussion). Employing mindfulness, acceptance, and cognitive defusion therapeutic strategies, ACT targets the role that experiential avoidance plays in maintaining and exacerbating psychological problems. Furthermore, contrary to traditional cognitive and CBT, ACT does not attempt to eliminate or suppress symptoms. Rather, ACT "seeks to ameliorate avoidance in the service of increasing the client's capacity to engage in a rich and meaningful life" (Wilson and Roberts, 2002: p. 238). That is, the goal of ACT is to live in accordance with one's core values as effectively as possible. Although symptom reduction often coincides with ACT therapy, symptom reduction is not the goal of ACT by any means but, perhaps, a therapeutic 'by-product' of sorts.

Although ACT is not as well established as other CBT (see Öst, 2008), preliminary findings suggest that ACT is effective for a number of conditions, including chronic pain (Dahl et al., 2004; Gutierrez et al., 2004; Johnston et al., 2010; McCracken et al., 2005; Vowles et al., 2008; Wicksell et al., 2009), depression (Forman et al., 2007), work-related stress and burnout (Bond and Bunce, 2000, 2003; Hayes et al., 2004), diagnosis acceptance (Blackledge and Hayes, 2006), panic disorder with agoraphobia (Carrascoso López, 2000), panic-related symptoms (Eifert and Heffner, 2003), generalized social anxiety disorder (Dalrymple and Herbert, 2007), self-harm (Gratz and Gunderson, 2006), relationship problems (Peterson et al., 2009), comorbid substance abuse and PTSD (Batten and Hayes, 2005), and comorbid depression and alcohol use disorders (Petersen and Zettle, 2009). Regarding meta-analytic reviews, as indicated, although ACT is superior to control and treatment as usual conditions (Hayes et al., 2006; Öst, 2008), it has not consistently been shown to be more effective than other more established treatments like CBT (Levin and Hayes, 2009; Powers et al., 2009; Ruiz, 2010).

DBT – another key player in the so-called third wave (according to some) – is arguably the most eclectic of the third-wave therapies. DBT appears much like applied behavior analysis with respect to behavioral chain analyses and basic case conceptualization (Linehan, 1993: pp. 258–264). Similarly, dialectical strategies, another core feature of DBT, are essentially cognitive reframing as seen in CT and CBT. Synthesizing theses and antitheses is one such example that bears a number of similarities to other cognitive approaches (e.g., recognizing that one's partner has both a beneficial and adverse effect on one's life; Linehan, 1993: pp. 120–124). DBT has the most empirical support with patients who engage in suicidal and parasuicidal behavior (e.g., cutting on or burning oneself) (Klonsky and Muehlenkamp, 2007). It, however, has recently been applied to other areas like eating disorders and substance abuse (Hill et al., 2011; Rizvi et al., 2011).

FAP – purportedly based on the principles of radical behaviorism – has not enjoyed the same degree of success as ACT or DBT (Kohlenberg and Tsai, 1991). Moreover, critics argue that there is little empirical support for FAP as a stand-alone therapy (Öst, 2008). Similar to the notions of transference and countertransference in psychoanalysis, FAP assumes that clinically relevant behavior (CRB) emerges in session within the context of the therapist–patient relationship. A CRB1 is the behavior that is problematic for the person (e.g., the client avoids intimacy or is quick to anger). After patients are taught to recognize CRB1s in therapy, other more adaptive, socially acceptable behavior is evoked and shaped by the therapist (CRB2). Eventually, the client or patient is taught to not only recognize and describe CRB1s and CRB2s but also elucidate the contingencies that are believed to influence them (CRB3s).

Ultimately, it is the aim of FAP to generalize this skill set shaped in the therapeutic milieu to daily life. As a side note, FAP is oftentimes used as a means of 'enhancing' or 'augmenting' CBT and ACT, as opposed to its use as a stand-alone therapy (e.g., Callaghan et al., 2004; Kohlenberg and Tsai, 1994; Kohlenberg et al., 2002). Its promise at 'enhancing' or 'augmenting' other therapies, notwithstanding, despite decades of theoretical work, FAP has produced only a modest amount of data showing its efficacy or effectiveness as a stand-alone therapy (Öst, 2008).

Charles Ferster (1973), a contemporary and major collaborator of B.F. Skinner (Ferster and Skinner, 1957), developed a functional analysis model of depression based on learning theory. Ferster maintained that individuals experience mood symptoms and engage in depressive behavior (e.g., crying, irritability, and hypersomnolence) when there is too little positive reinforcement and too much negative reinforcement (or punishment). Specifically, negative contingencies tend to narrow behavioral repertoires which, in turn, results in fewer opportunities of accessing positive reinforcers or, in common parlance, 'pleasant events.' For example, an abused spouse who avoids leaving her partner due to fear of retaliation and/or 'being alone' may never find a more suitable partner with whom she might build a more healthy relationship. Moreover, the constant threat of verbal and physical abuse that is contingent on her behaving or not behaving in accordance with her partner's rigid expectations (i.e., aversive control) narrows her behavioral repertoire, such that she almost invariably focuses only on 'doing what she is told.' The exploratory behavior of seeking a meaningful profession, advancing her education, or establishing new relationships in the area, in contrast, would most likely decrease in frequency under these prevailing contingencies. In those circumstances, of course, these women are at elevated risk for developing depression. In a recent meta-analysis, for example, women exposed to intimate partner violence were at significantly elevated risk for major depressive disorder, dysthymia, mild depression, or suicide attempts (Devries et al., 2013). Although one could not say definitively what caused their depression as these are correlational studies, one might assume that their mood symptoms are due in part to increased rates of negative reinforcement (and punishment) and decreased access to positive reinforcement.

Lewinsohn and colleagues expanded upon and laid the empirical foundations for Ferster's model (Lewinsohn et al., 1976). Lewinsohn and colleagues proposed that depressed individuals experience low rates of what they called response-contingent positive reinforcers (i.e., the behavior is causally linked to the positive reinforcer or class of reinforcers). There are several pathways by which this might

occur. First, the environment might simply change such that the reinforcer becomes less available (e.g., a best friend at work is transferred to another facility). Two, reinforcers might lose their effectiveness over time (e.g., perhaps, through habituation or other classical conditioning processes). Three, though the reinforcer is still available, the individual's behavior loses potency at accessing it, especially in the context of competitive arrangements (e.g., a potential love interest becomes more interested in a new employee whose behavior is more reinforcing of his attention). The goal of Lewinsohn et al.'s treatment is, therefore, to reinstate the rate of response-contingent positive reinforcers to previous baseline levels (or, ideally, foster higher rates). Lewinsohn and colleagues developed the *Pleasant Events Schedule* for this reason: to assist patients in identifying potential reinforcers (MacPhillamy and Lewinsohn, 1982).

Influenced by the work of Ferster and Lewinsohn and colleagues, and based on a rather compelling component analysis of CBT conducted by Neil Jacobson and colleagues (Jacobson et al., 1996) – where they found that CBT produced comparable outcomes when compared to BT alone (also see Dimidjian et al., 2006; Gortner et al., 1998, for similar findings) – Jacobson and colleagues developed a new treatment called BA therapy (Jacobson et al., 2001). Unfortunately, Jacobson passed away suddenly before his work reached fruition and was subsequently published. Accordingly, his colleagues continued the work that culminated in the book titled *Depression in Context: Strategies for Guided Action* (Martell et al., 2001).

The BA approach views depression from a contextual and functional perspective. It maintains that life events can disrupt regular behavioral patterns or, more technically, prevailing schedules or reinforcement (e.g., job loss, divorce, death of friends or family members). While some individuals tend to bounce back from adversity, other individuals – particularly those who employ passive coping styles – are more likely to develop depression. Passive coping strategies includes, though is not limited to, excessive sleeping, social isolation, excessive alcohol, or cannabis use. Although effective in the short term, these approaches often compound problems later on. Excessive sleeping might result in chronic insomnia due to disruption of one's normal sleep–wake schedule. Social isolation can eventuate in losing friends over time. Of course, chronic alcohol or cannabis use can result in abuse or dependence.

BA focuses on increasing access to reinforcement and developing more active behavioral coping strategies. In other words, BA sees avoidance behavior as the primary therapeutic target. Among other strategies, BA employs the use of various heuristics in assisting patients in first identifying problematic avoidance patterns (TRAP – Trigger, Response, Avoidance Pattern) and, second, discovering active, more effective coping styles (TRAC – Trigger, Response, Alternative Coping) (Martell et al., 2001).

While there are fewer empirical studies on BA relative to other third-wave therapies (DBT and ACT in particular), it has been shown to be effective in clinical settings, especially with depressed patients (Coffman et al., 2007; Cuijpers et al., 2007; Dimidjian et al., 2006; Jacobson et al., 2001).

Some authors, however, have argued that some of these therapies have been oversold and might not fit within the general properties of an evidence-based orientation of behavior therapy (O'Donohue et al., 2014). For example, the practice of mindfulness does not lend itself well to most behavioral interpretations. Mindfulness is neither a classical conditioning nor an operant conditioning process. Rather, mindfulness, as framed in ACT, is used to "pierce the illusion of language … like an audience that learns how a magic trick is accomplished" (Hayes, 2002). That is to say, it is a therapeutic strategy by which patients learn to contact contingencies of reinforcement and extricate themselves from obstructive rule following (e.g., "panic attacks are deadly"; Hayes, 1989; Zettle, 1990). It seems fair to say that first-generation behavior therapists were much more interested and allied with various behaviorisms (see O'Donohue and Kitchener, 1997) and this kind of speaking about the mind, for them, was quite problematic.

Conclusions

The purpose of this article was to provide a broad outline of second- and third-wave therapies. First-generation or first-wave behavior therapy developed out of dissatisfaction with psychoanalysis. Although first-wave behavior therapy showed promise in treating intractable conditions that eluded psychoanalysts at the time, it eventually gave rise to the second wave of behavior therapy. Second-wave behavior therapists were successful at treating a number of complex psychiatric disorders including recurrent depression, PTSD, panic disorder, and OCD.

The third wave supposedly developed out of dissatisfaction with the second wave of behavior therapy. The third wave introduced a number of new concepts and terms into the behavioral canon including metacognition, cognitive fusion, emotional regulation, acceptance, mindfulness, and dialectics. The third wave, of course, might have been oversold and may not actually fit within the general properties of an evidence-based orientation of behavior therapy. Moreover, while the third wave – especially ACT and DBT – have risen in stature within a short while (since the 1990s), many clinicians identify themselves as eclectic and thus employ a hybrid approach, cobbling principles and practices from CBT, ACT, and DBT (Jensen et al., 1990). However, it is fair to say that these waves also produce heterogeneity in the practice of behavior therapy as individual behavior therapists have various interests and allegiances to each of the waves.

Abstract

Behavioral economics is the combination of psychology and economics that investigates what happens in markets in which some of the agents display human limitations and complications. We begin with a preliminary question about relevance. Does some combination of market forces, learning, and evolution render these human qualities irrelevant? No. Because of limits of arbitrage, less than perfect agents survive and influence market outcomes. We then discuss three important ways in which humans deviate from the standard economic model. Bounded rationality reflects the limited cognitive abilities that constrain human problem solving. Bounded willpower captures the fact that people sometimes make choices that are not in their long-term interest. Bounded self-interest incorporates the comforting fact that humans are often willing to sacrifice their own interests to help others. We then illustrate how these concepts can be applied in two settings: finance and savings. Financial markets have greater arbitrage opportunities than other markets, so behavioral factors might be thought to be less important here, but we show that even here the limits of arbitrage create anomalies that the psychology of decision making helps to explain. Since saving for retirement requires both complex calculations and willpower, behavioral factors are essential elements of any complete descriptive theory.

It says something interesting about the field of economics that there is a subfield called behavioral economics. Surely all of economics is meant to be about the behavior of economic agents, be they firms or consumers, suppliers or demanders, bankers or farmers. So, what is behavioral economics, and how does it differ from the rest of economics?

Economics traditionally conceptualizes a world populated by calculating, unemotional maximizers that have been dubbed *Homo economicus*. In a sense, neoclassical economics has defined itself as explicitly 'antibehavioral.' Indeed, virtually all the behavior studied by cognitive and social psychologists is either ignored or ruled out in a standard economic framework. This unbehavioral economic agent has been defended on numerous grounds: some claimed that the model was 'right'; most others simply argued that the standard model was easier to formalize and practically more relevant.

Behavioral economics blossomed with the realization that neither point of view was correct. Empirical and experimental evidence mounted against the stark predictions of unbounded rationality. Further work made clear that one could formalize psychological ideas and translate them into testable predictions. The behavioral economics research program has consisted of two components: (1) identifying the ways in which behavior differs from the standard model and (2) showing how this behavior matters in economic contexts.

This article gives a flavor of the program. We begin by discussing the most important ways in which the standard economic model needs to be enriched. We then illustrate how behavioral economics has been fruitfully applied to two important fields: finance and savings. However, first, we discuss why the market forces and learning do not eliminate the importance of human actions.

Is Homo Economicus the Only One Who Survives?

Many economists have argued that a combination of market forces (competition and arbitrage) plus evolution should produce a world similar to that described in an economics textbook: do only the rational agents survive? Or, do the workings of markets at least render the actions of the quasi-rational irrelevant? These are questions that have been much studied since the 1980s, and the early impressions of many economists that markets would wipe out irrationality were optimistic.

Consider a specific example: human capital formation. Suppose that a young economist, named Sam, decides to become a behavioral economist, perhaps because he mistakenly thinks this will lead to riches, or because he thinks it is going to be the next fad, or because he finds it interesting and lacks the willpower to study 'real' economics. Whatever the reason for the choice, let us assume for the sake of argument that this decision was a mistake for Sam by any rational calculation. So, what will market forces do? First, Sam may be poorer because of this choice than if he had sensibly chosen to study corporate finance, but he will not be destitute. Sam might even realize that he could switch to corporate finance and make much more money but is simply unable to resist the temptation to continue wasting his time on behavioral economics. So, markets per se do not necessarily solve the problem: they provide an *incentive* to switch, but they cannot force Sam's hand.

What about arbitrage? In this case, like most things we study in economics outside the realm of financial markets, there is simply no arbitrage opportunity available. Suppose a wise arbitrageur is watching Sam's choices, what bet can he or she place? None. The same can be said if Sam saves too little for retirement, picks the wrong wife, or buys the wrong car. None of these irrational acts generates an arbitrage opportunity for anyone else.

Indeed, economists now realize that even in financial markets there are important limits to the workings of arbitrage. First, in the face of irrational traders, the arbitrageur may privately benefit more from trading that helps push prices in the wrong direction than from trading that pushes prices in the

right direction. Put another way, it may often pay 'smart money' to follow 'dumb money' rather than to lean against it (Haltiwanger and Waldman, 1985; Russell and Thaler, 1985). For example, an extremely smart arbitrageur near the beginning of the tulip mania would have profited more from buying tulips and further destabilizing prices than by shorting them. Second, and slightly related, arbitrage is an inherently risky activity and consequently the supply of arbitrage will be inherently limited (De Long et al., 1990). Arbitrageurs who did decide to short tulips early would probably have been wiped out by the time their bets were proven to be 'right.' Add to this the fact that in practice most arbitrageurs are managing other people's money and therefore judged periodically, one can see the short horizons that an arbitrageur will be forced to take on. This point was made forcefully by Shleifer and Vishny (1997), who essentially foresaw the scenario that ended up closing Long-term Capital Management.

So, markets per se cannot be relied upon to make economic agents rational. What about evolution? An old argument was that individuals who failed to maximize should have been weeded out by evolutionary forces, which presumably operated during ancient times. Overconfident hunters, for example, presumably caught less prey, ate less, and died younger. Such reasoning, however, has turned out to be faulty. Evolutionary arguments can just as readily explain over-confidence as they can explain appropriate levels of confidence. For example, consider individuals playing a war of attrition (perhaps in deciding when to back down during combat). Here over-confidence will actually help. Seeing the overconfidence, a rational opponent will actually choose to back down sooner. As can be seen from this example, depending on the initial environment (especially when these environments have a game theoretic component to them), evolution may just as readily weed out rational behavior as it does weed out quasi-rational behavior. The troubling flexibility of evolutionary models means that they can just as readily argue for bounds on rationality.

The final argument is that individuals who systematically and consistently make the same mistake will eventually learn the error of their ways. This kind of argument has also not stood up well under theoretical scrutiny. First, the optimal experimentation literature has shown that there can be a complete lack of learning even in infinite horizons. The intuition here is simple: as long as there are some opportunity costs to learning or to experimenting with a new strategy, even a completely 'rational' learner will choose not to experiment. This player will get stuck in a non-optimal equilibrium, simply because the cost of trying something else is too high. Second, work on learning in games has formally demonstrated Keynes' morbid observation on the 'long run.' The time required to converge to an equilibrium strategy can be extremely long. Add to this a changing environment and one can easily be in a situation of perpetual nonconvergence. In practice, for many of the important decisions we make, both arguments apply with full force. The number of times we get to learn from our retirement decisions is low (and possibly zero). The opportunity cost of experimenting with different ways of choosing a career can be very high.

The upshot of all these theoretical innovations has been clear. One cannot defend unbounded rationality on purely theoretical grounds. Neither arbitrage, competition, evolution, nor learning necessarily guarantees that unbounded rationality must be an effective model. In the end, as some might have expected, it must ultimately be an empirical issue. Does 'behavior' matter? Before evaluating this question in two different fields of application, we explore the ways in which real behavior differs from the stylized neoclassical model.

Three Bounds of Human Nature

The standard economic model of human behavior includes (at least) three unrealistic traits: unbounded rationality, unbounded willpower, and unbounded selfishness. These three traits are good candidates for modification.

Herbert Simon (1955) was an early critic of modeling economic agents as having unlimited information processing capabilities. He suggested the term 'bounded rationality' to describe a more realistic conception of human problem solving capabilities. As stressed by Conlisk (1996), the failure to incorporate bounded rationality into economic models is just bad economics – the equivalent to presuming the existence of a free lunch. Since we have only so much brainpower, and only so much time, we cannot be expected to solve difficult problems optimally. It is eminently 'rational' for people to adopt rules of thumb as a way to economize on cognitive faculties. Yet the standard model ignores these bounds and hence the heuristics commonly used. As shown by Kahneman and Tversky (1974), this oversight can be important since sensible heuristics can lead to systematic errors.

Departures from rationality emerge both in judgments (beliefs) and in choice. The ways in which judgment diverges from rationality is long and extensive (Kahneman et al., 1982). Some illustrative examples include overconfidence, optimism, anchoring, extrapolation, and making judgments of frequency or likelihood based on salience (the availability heuristic) or similarity (the representativeness heuristic).

Many of the departures from rational choice are captured by prospect theory (Kahneman and Tversky, 1979), a purely descriptive theory of how people make choices under uncertainty (see Starmer (2000) for a review of literature on non-EU theories of choice). Prospect theory is an excellent example of a behavioral economic theory in that its key theoretical components incorporate important features of psychology. Consider three features of the prospect theory value function. (1) It is defined over changes to wealth rather than levels of wealth (as in EU) to incorporate the concept of adaptation. (2) The loss function is steeper than the gain function to incorporate the notion of 'loss aversion'; the notion that people are more sensitive to decreases in their well being than to increases. (3) Both the gain and loss function display diminishing sensitivity (the gain function is concave, the loss function convex) to reflect experimental findings. To describe fully choices prospect theory often needs to be combined with an understanding of 'mental accounting' (Thaler, 1985). One needs to understand when individuals faced with separate gambles treat them as separate gains and losses and when they treat them as one, pooling them to produce one gain or loss.

A few examples can illustrate how these concepts are used in real economics contexts. Consider overconfidence. If investors are overconfident in their abilities, they will be willing to make

trades even in the absence of true information. This insight helps explain a major anomaly of financial markets. In an efficient market when rationality is common knowledge, there is virtually no trading, but in actual markets there are hundreds of millions of shares traded daily and most professionally managed portfolios are turned over once a year or more. Individual investors also trade a lot: they incur transaction costs and yet the stocks they buy subsequently do worse than the stocks they sell.

An example involving loss aversion and mental accounting is Camerer et al.'s (1997) study of New York City cab drivers. These cab drivers pay a fixed fee to rent their cabs for 12h and then keep all their revenues. They must decide how long to drive each day. A maximizing strategy is to work longer hours on good days (days with high earnings per hour such as rainy days or days with a big convention in town) and to quit early on bad days. However, suppose cabbies set a target earnings level for each day, and treat shortfalls relative to that target as a loss. Then, they will end up quitting early on good days and working longer on bad days, precisely the opposite of the rational strategy. This is exactly what Camerer et al. found in their empirical work.

Having solved for the optimum, *Homo economicus* is next assumed to choose the optimum. Real humans, even when they know what is best, sometimes fail to choose it for self-control reasons. Most of us at some point have eaten, drunk, or spent too much, and exercised, saved, or worked too little: such is human nature. People (even economists) also procrastinate. We are completing this article after the date on which it was due, and we are confident that we are not the only guilty parties. Although people have these self-control problems, the are at least somewhat aware of them: they join diet plans and buy cigarettes by the pack (because having an entire carton around is too tempting). They also pay more withholding taxes than they need to (in 1997, nearly 90 million tax returns paid an average refund of around $1300) in order to assure themselves a refund, but then file their taxes near midnight on April 15 (at the post office that is being kept open late to accommodate their fellow procrastinators).

Finally, people are boundedly selfish. Although economic theory does not rule out altruism, as a practical matter economists stress self-interest as the primary motive. For example, the free rider problems widely discussed in economics are predicted to occur because individuals cannot be expected to contribute to the public good unless their private welfare is thus improved. In contrast, people often take selfless actions. In 1993, 73.4% of all households gave some money to charity, the average dollar amount being 2.1% of household income. Also, 47.7% of the population does volunteer work with 4.2h per week being the average time volunteered. Similar selfless behavior is observed in controlled laboratory experiments. Subjects systematically often cooperate in public goods and prisoners dilemma games, and turn down unfair offers in 'ultimatum' games.

Finance

If economists had been polled around 1980 and asked to name the domain in which bounded rationality was least likely to find useful applications the likely winner would have been finance. The limits of arbitrage arguments were not well understood at that time, and one leading economist had called the efficient markets hypothesis the best established fact in economics. Times change. As we begin the twenty-first century finance is perhaps the branch of economics where behavioral economics has made the greatest contributions. How has this happened?

Two factors contributed to the surprising success of behavioral finance. First, financial economics in general, and the efficient market hypothesis in particular, generated sharp, testable predictions about observable phenomena. Second, there are many data readily available to test these sharp predictions. We briefly summarize here a few examples.

The rational efficient markets hypothesis makes two classes of predictions about stock price behavior. The first is that stock prices are 'correct' in the sense that asset prices reflect the true or rational value of the security. In many cases this tenet of the efficient market hypothesis is untestable because intrinsic values are not observable. However, in some special cases the hypothesis can be tested by comparing two assets whose relative intrinsic values are known. One class of these is called 'Siamese Twins': two versions of the same stock that trade in different places.

A specific well-known example is the case of Royal Dutch Shell as documented in Froot and Dabora (1999). The facts are that Royal Dutch Petroleum and Shell Transport are independently incorporated in The Netherlands and the UK, respectively. The current firm emerged from a 1907 alliance between Royal Dutch and Shell Transport in which the two companies agreed to merge their interests on a 60:40 basis. Royal Dutch trades primarily in the USA and The Netherlands and Shell trades primarily in London. According to any rational model, the shares of these two components (after adjusting for foreign exchange) should trade in a ratio of 60:40. They do not; the actual price ratio has deviated from the expected one by more than 35%. Simple explanations such as taxes and transactions costs cannot explain the disparity (see Froot and Dabora, 1999). This example illustrates that prices can diverge from intrinsic value because of limits of arbitrage. Some investors do try to exploit this mispricing, buying the cheaper stock and shorting the more expensive one, but this is not a sure thing, as many hedge funds learned in the summer of 1998 (when, at the time hedge funds were trying to get more liquidity, the pricing disparity widened).

The Royal Dutch Shell anomaly is a violation of one of the most basic principles of economics: the law of one price. Another similar example is the case of closed-end mutual funds (Lee et al., 1991). These funds are much like typical (open-end) mutual funds except that to cash out of the fund, investors must sell their shares on the open market. This means that closed-end funds have market prices that are determined by supply and demand, rather than set equal to the value of their assets by the fund managers as in an open-end fund. Since the holdings of closed-end funds are public, market efficiency would lead one to expect that the price of the fund should match the price of the underlying securities they hold (the net asset value or NAV). Instead, closed-end funds typically trade at substantial discounts relative to their NAV, and occasionally at substantial premiums. Most interesting from a behavioral perspective is that closed-end fund discounts are correlated

with one another and appear to reflect individual investor sentiment. (Closed-end funds are owned primarily by individual investors rather than institutions.) Lee et al. found that discounts shrink in months when shares of small companies (also owned primarily by individuals) do well, and in months when there is lots of IPO activity, indicating a 'hot' market. Since these findings were predicted by their theory, they move the research beyond the demonstration of an embarrassing fact (price not equal to NAV) toward a constructive understanding of how markets work.

The second principle of the efficient market hypothesis is 'unpredictability.' In an efficient market it is not possible to predict future stock price movements based on publicly available information. Many early violations of this had no explicit link to behavior. Thus it was reported that small firms, firms with low price–earnings ratios earned higher returns than other stocks with the same risk. Also, stocks in general, but especially stocks of small companies, have done well in January and on Fridays (but poorly on Mondays).

An early study by De Bondt et al. (1985) was explicitly motivated by the psychological finding that individuals tend to over-react to new information. For example, experimental evidence suggests that people tended to underweight base-rate data (or prior information) in incorporating new data. De Bondt et al. hypothesized that if investors displayed this behavior, then stocks that had performed fairly well over a period of years will eventually have prices that are too high. Individuals over-reacting to the good news will drive the prices of these stocks too high. Similarly, poor performers will eventually have prices that are too low. This yields a prediction about future returns: past 'winners' ought to underperform while past 'losers' ought to outperform the market. Using data for stocks traded on the New York Stock Exchange, De Bondt et al. (1985) found that the 35 stocks that had performed the worst over the past 5 years (the losers) outperformed the market over the next 5 years, while the 35 biggest winners over the past 5 years subsequently underperformed. Follow-up studies have shown that these early results cannot be attributed to risk (by some measures the portfolio of losers is actually less risky than the portfolio of winners), and can be extended to other measures of over-reaction such as the ratio of market price to the book value of equity.

More recent studies have found other violations of unpredictability that have the opposite pattern from that found by DeBondt et al., namely under-reaction rather than over-reaction. Over short periods of time, e.g., 6 months to 1 year, stocks display momentum – the stocks that go up the fastest for the first 6 months of the year tend to keep going up. Also, after many corporate announcements such as large earnings changes, dividend initiations and omissions, share repurchases, splits, and seasoned equity offerings, there is an initial price jump on the day of the announcement followed by a slow drift in the same direction for as long as 1 year or more (Shleifer, 2000).

These findings of under-reaction are a further challenge to the efficient markets hypothesis, but also to behavioral finance. Do markets sometimes over-react, and sometimes under-react? If so, can *any* pattern be explained, at least *ex post*? Is there a unifying framework that can bring together these apparently opposing facts and ideas?

Work is only now beginning to attack this extremely important question. Several explanations have beenoffered recently (Shleifer (2000) summarizes them). All rely on psychological evidence (in one way or another) in unifying the facts. They all explain the anomalies by noting that under-reaction appears at short horizons whereas over-reaction appears at longer horizons, but each paper provides its own distinctive explanation. Which (if any) of these is the best one has yet to be decided. But the facts discovered so far, combined with these models, demonstrate the changing nature of finance. Rigorous empirical work building on psychological phenomena has given us new tools to unearth interesting empirical facts. Rigorous theoretical work, on the other hand, has been trying to address the challenge of incorporating these empirical facts into a psychologically plausible model.

The research discussed so far has been about asset prices and the controversy about the efficient market hypothesis. There is another stream of research that is just about investor behavior, not about prices. One example of this stream is motivated by mental accounting and loss aversion. The issue is whether investors are reluctant to realize capital losses (because they would have to 'declare' the loss to themselves). Shefrin and Statman (1985) dubbed this hypothesis the 'disposition effect.' The prediction that investors will be less willing to sell a loser than a winner is striking since the tax law encourages just the opposite behavior. Nevertheless, Odean (1998) finds evidence of just this behavior. In his sample of the customers of a discount brokerage firm, investors were more likely to sell a stock that had increased in value than one that had decreased in value. While around 15% of all gains were realized, only 10% of all losses are realized. This hesitancy to realize gains came at a cost. Odean shows that the stocks the loser stocks held under-performed the gainer stocks that were sold.

Savings

If finance was the field in which a behavioral approach was least likely, *a priori*, to succeed, saving had to be one of the most promising. The standard life-cycle model of savings abstracts from both bounded rationality and bounded willpower, yet saving for retirement is both a difficult cognitive problem and a difficult self-control problem. It is then, perhaps less surprising that a behavioral approach has been fruitful here. As in finance, progress has been helped by the combination of a refined standard theory with testable predictions and many data sources on household saving behavior. One crisp prediction of the life-cycle model is that savings rates are independent of income. Suppose twins Tom and Ray are identical in every respect except that Tom earns most of his money early in his life (e.g., he is a basketball player), whereas Ray earns most of his late in life (e.g., he is a manager). The life-cycle model predicts that Tom the basketball player ought to save his early income to increase consumption later in life, whereas Ray the manager ought to borrow from his future income to increase consumption earlier in life. This prediction is completely unsupported by the data, which show that consumption very closely tracks income over individuals' life cycles. Furthermore, the

departures from predicted behavior cannot be explained merely by people's inability to borrow. Banks et al. (1998) show, for example, that consumption drops sharply as individuals retire and their incomes drop. They have simply not saved enough for retirement. Indeed, many low- to middle-income families have essentially no savings whatsoever. The primary cause of this lack of saving appears to be self-control. One piece of evidence supporting this conclusion is that virtually all saving done by Americans is accomplished in vehicles that support what are often called 'forced savings,' e.g., accumulating home equity by paying the mortgage and participation in pension plans. Coming full circle, one 'forced' savings that individuals may choose themselves may be high tax withholdings, so that when the refund comes they can buy something they might not have had the willpower to save up for.

One of the most interesting research areas has been devoted to measuring the effectiveness of tax-subsidized savings programs such as IRAs and 401(k)s. The standard analysis of these programs is fairly simple. Consider the original IRA program from the early 1980s. This program provided tax subsidies for savings up to a threshold, often $2000 per year; there was no marginal incentive to save for any household that was already saving more than $2000 per year. Therefore, those saving more than the threshold should not increase their total saving, they will merely switch some money from a taxable account to the IRA for the tax gain. Moreover, everyone who is saving a positive amount should participate in this program for the infra-marginal gain. The actual analysis of these programs has shown that the reality is not so clear. By some accounts at least, these programs appear to have generated considerable new savings. Some argue that almost every dollar of savings in IRAs appears to represent new savings. In other words, people are not simply shifting their savings into IRAs and leaving their total behavior unchanged. Similar results are found for 401(k) plans. The behavioral explanation for these findings is that IRAs and 401(k) plans help solve self-control problems by setting up special mental accounts that are devoted to retirement savings. Households tend to respect the designated use of these accounts, and their self-control is helped by the tax penalty that must be paid if funds are removed prematurely. (Some issues remain controversial. See the debate in the Fall, 1996 issue of the *Journal of Economic Perspectives*.)

An interesting flip side to IRA and 401(k) programs is that they also generated far less than the full participation one would have expected. Many eligible people do not participate, foregoing in effect a cash transfer from the government (and, in some cases, from their employer). O'Donoghue and Rabin (1999) present an explanation based on procrastination and hyperbolic discounting. Individuals typically show very sharp impatience for short-horizon decisions, but much more patience at long horizons. This is often referred to as hyperbolic discounting by contrast with the standard assumption of exponential discounting, in which patience is independent of horizon. In exponential models, people are equally patient at long and short horizons. O'Donoghue and Rabin argue that hyperbolic individuals will show exactly the low IRA participation that we observe. Although hyperbolic people will want eventually to participate in IRAs (because they are patient in the long run), something always comes up in the short run (where they are very impatient) that provides greater immediate reward. Consequently, they may delay joining the IRA indefinitely.

If people procrastinate about joining the savings plan, then it should be possible to increase participation rates simply by lowering the psychic costs of joining. One simple way of accomplishing this is to switch the default option for new workers. In most companies, when employees first become eligible for the 401(k) plan, they receive a form inviting them to join; to join they have to send the form back and make some choices. Several firms have made the seemingly inconsequential change of switching the default: employees are enrolled into the plan unless they explicitly opt out. This change has often produced dramatic increases in savings rates. For example, in one company studied by Madrian and Shea (2000), the employees who joined after switching the default to being in the plan were 50% more likely to participate than the workers in the year prior to the change. (They also found that the default asset allocation had a strong effect on workers' choices. The firm had made the default asset allocation 100% in a money market account, and the proportion of workers selecting this allocation soared.)

Along with these empirical facts, there has also been substantial theoretical work. To cite a few examples, Laibson (1997) and O'Donoghue and Rabin (1999) both examined the effects of hyperbolic discounting on the savings decisions. They highlighted that hyperbolic individuals will demand commitment devices (savings vehicles which are illiquid) and generally fail to obey the Euler equation.

Other Directions

We have concentrated on two fields here in order to give a sense of what behavioral economics can do, but we do not want to leave the impression that savings and financial markets are the only domains in which a behavioral approach has been or could be effective. In labor economics, experimental and empirical work has underlined the importance of fairness considerations in setting wages. For example, wages between industries differ dramatically, even for identical workers and, most interestingly, even homogeneous workers (such as janitors) earn higher wages when they work in industries where other occupations earn more. In law and economics, we have seen the importance of 'irrelevant' factors in a jury's decision to sentence or in the magnitude of awards they give. In corporate finance, one can fruitfully interpret a manager's decision to acquire or diversify as resulting from overconfidence. One could go on. There is much to be done.

Editor's Note

Thirty years ago, behavioral economics did not exist as a systematic field of inquiry; today, it is one of the most active and exciting areas of research within economics. Abstract

This article reviews the historical development of behavioral economics, with an emphasis on how it has become part of mainstream economics. First I describe the separation between economics and psychology as a historical background against which behavioral economics emerged. Then I introduce critiques of expected utility theory (EUT), and explain how behavioral decision research developed using EUT as an experimental paradigm. I then distinguish 'old,' 'new,' and 'second-wave' behavioral economics, and briefly discuss criticisms of the last.

Introduction

Behavioral economics, an increasingly influential research program in economics, tries to improve economic theory and policy by drawing mainly on psychological or behavioral insights on how real people, as opposed to the idealistically rational agent, think and behave (Mullainathan and Thaler, 2001; Camerer and Loewenstein, 2004). Behavioral economics thus defined has now become part of mainstream economics, in terms of the numbers of behavioral economists hired in research institutions, journal articles, and textbooks published, and prestigious prizes awarded to behavioral economists. Its practical relevance is increasing as both public and private sectors use more findings from behavioral economics to efficiently and effectively change people's behavior. Finally, several popular books (e.g., Ariely, 2008; Poundstone, 2010; Kahneman, 2013) made behavioral economics well known among the educated general public. Accordingly, an interest in its history has arisen as well. Sent (2004) is one of the earliest studies on this subject, and Angner and Loewenstein (2012) is an informative review. Heukelom (2014) gives a book-length treatment (see also Heukelom, 2011, 2012). One of the questions these authors explicitly and implicitly ask is why behavioral economics has been so successful. There are several contributing factors, and the reader is referred to the above mentioned literature to get a fuller account. In this article, I will highlight one important reason for the success of behavioral economics, namely that it adopted mainstream rational economic modeling tools such as utility maximization and equilibrium analysis of games, instead of denying them and proposing an altogether different approach.

The article proceeds as follows: Section The Historical Context briefly introduces the historical background against I proceed as follows: after briefly introducing The Historical Context in which behavioral economics emerged, I describe Early Criticisms of EUT and describe 'Old' Behavioral Economics. Then I identify Behavioral Decision Research (BDR) as a basis of 'New' Behavioral Economics, and describe two important results in BDR, which gave rise to 'New' Behavioral Economics. Then I illustrate The 'Second-Wave' Behavioral Economics and its critics, followed by Conclusion.

The Historical Context

Economics as a Separate Science

If behavioral economics is characterized by the use of rich psychological insights, then its history has to go back at least to David Hume (1711–76) and Adam Smith (1723–90). In fact, Ashraf et al. (2005) argue that Smith's *Theory of Moral Sentiments* (Smith, 2002, first published in 1759) proposes what is now called the dual-process cognitive model; anticipates modern findings such as loss aversion, willpower, and fairness; and even suggests new directions for research in behavioral economics. Even though these claims might well be true, it is important to remember that contemporary behavioral economics has emerged against a backdrop of the sharp separation of economics from psychology that had been gradually established over 200 years since Smith. This separation started from John Stuart Mill's (1806–73) deductive and a priori methodology, and was achieved by successive neoclassical theoretical innovations such as marginal utility theory, indifference curve analysis, and revealed preference theory. As a result, economists became able to model an agent's choice behavior in terms of her preference satisfaction without referring to the utility concept connected with psychological valence. Instead, the concept of utility was reinterpreted simply as a mathematically useful way of representing preference orderings as defined by preference theory.

Subjective Expected Utility Theory

Preference theory made it possible to explain choice behavior in terms of preference orderings. In turn, the utility concept in economics became 'ordinal,' i.e., there was no need to talk about subjective and unobservable intensities of psychological utilities for different goods. This situation was somewhat complicated by the invention of expected utility theory (EUT). In general, desirability of a course of action depends not only on the value that action intends to deliver, but also on (one's belief about) the way the world is; for instance, the desirability of an action of bringing or not bringing an umbrella depends on what (one thinks) the weather is going to be like. In order to model decision-making under such uncertainty, the British philosopher Frank Ramsey (1903–30) sketched, in 1926, a way of quantifying and operationalizing degrees of beliefs and

desires solely from the observation of the agent's simple choices over lotteries, adopting an idealized folk psychological scheme in which "we act in the way we think most likely to realize the objects of our desires, so that a person's actions are completely determined by his desires and opinions"(Ramsey, 1931: 173). The mathematician John von Neumann (1903–57), while working on the theory of strategic interactions and its application to economics, axiomatized this system as EUT (von Neumann and Morgenstern, 2004, originally published in 1944). (The full axiomatization is given in the second edition published in 1947.) von Neumann and Morgenstern (2004) proposed the objective interpretation of probability (i.e., as relative frequencies of events in the long run), but anticipated subjective EUT, admitting that the subjective view of probability also leads to a satisfactory numerical concept of utility (3.3.3: fn. 2). The mathematician Leonard Savage (1917–71), a war-time assistant of von Neumann at the Institute for Advanced Study, Princeton, completed the subjective version of EUT, the foundation of modern decision theory (Savage, 1954). (The idea of expected utility itself was already proposed by the Dutch-Swiss mathematician Daniel Bernoulli (1700–82) in 1738. Another important founder of subjective EUT is the Italian statistician Bruno de Finetti (1906–85), whose work is acknowledged in Savage (1954).) As a result, it became possible to talk about the relative intensity of preferences in an operationally meaningful and principled way, bringing the 'cardinal' utility back in economic models of decision-making in a legitimate fashion. At the same time, Savage's theory made it possible to measure subjective beliefs *qua* probabilities in an equally rigorous manner. As we will see below, the birth of EUT proved to be crucial for the emergence of behavioral economics. (In what follows, I simply use the term EUT, but this should be read as a subjective version of the theory unless otherwise stated.)

Early Criticisms of EUT

Savage's EUT is not behavioristic as preference theory presumably aspired to be, because the former explicitly refers to psychological constructs such as subjective beliefs and expected utility. Nevertheless, economists welcomed it because the axiomatic approach was thought to guarantee the operationally meaningful and nonarbitrary measurement of these quantities. EUT thus soon found its application in economics. As early as 1948, Milton Friedman (1912–2006) collaborated with Savage, putting forward EUT as an economic hypothesis to explain the coexistence of insurance and lotteries (Friedman and Savage, 1948). But no sooner than EUT was completed as an axiomatic system, several economists expressed serious doubts on its normative acceptability and empirical plausibility (Markowitz, 1952; Allais, 1953; Ellsberg, 1961). These criticisms, however, were based on introspection and casual observations, rather than the rigorous experimental studies. This is only natural because back in the days experimental methods were not part of economists' toolbox yet. Instead, early experimental tests of EUT, with small but real monetary incentives, were conducted by the Harvard statistician Frederick Mosteller (1916–2006) and his student Philip Nogee (1951), and by the psychologist Sidney Siegel (1916–61), philosophers Donald Davidson (1917–2003), and Patrick Suppes (1922 to present) at Stanford (Stanford Value Theory Project) (1955). Another student of Mosteller, Ward Edwards (1927–2005), played a particularly important role in the rise of behavioral economics, as we will see in the next section. Before discussing that, I will turn to the so-called 'old' behavioral economics below.

'Old' Behavioral Economics

Herbert Simon (1916–2001), one of the earliest critics of models of rational choice in economics, was more radical than his contemporary critics of EUT. While these critics formulated problems as implausibility of specific axioms of EUT, such as the independent axiom, Simon offered a more programmatic critique, as part of the broader contribution he made to the so-called cognitive revolution: a paradigm shift in the postwar psychology from behaviorism to the computational modeling of internal cognitive processes. Simon argued that utility maximization models such as EUT, interpreted as representational models of cognitive processes of economic agents, are empirically unsound, drawing on the distinction between *substantive* and *procedural* rationality. The former concerns an intelligent system's adjustment or adaptation to its outer environment (e.g., an economic agent's reaction to the market), whereas the latter concerns the system's ability determined by its inner knowledge and computation that constrains the former (Simon, 1996: 25). A key idea is that we need only substantive rationality to predict behavior of the system *if* both its goal and environment are simple; but since these factors and their interaction are in fact complex, Simon argued, we have to explicitly consider the procedural rationality of the system. From this *bounded rationality* perspective, economic models of choice are deficient because they assume substantive rationality (individuals' utility maximization and organizations' profit maximization in the market environment) when in fact these conditions are not satisfied, requiring the explicit modeling of the inner workings of the agent, be it a human being or a firm.

Simon's impact on mainstream economics, however, was limited. Although he received the Nobel Memorial Prize in Economics in 1978 "for his pioneering research into the decision-making process within economic organizations," his proposal that *individual* procedural rationality should be explicitly modeled was not accepted by mainstream economics. Neither were his contemporary economists' alternative methods and theories that drew on psychology and other social sciences. Although already in the 1960s the term 'behavioral economics' was used to refer to these economists' rather heterogeneous research programs (Sent, 2004), their efforts did not have much impact on mainstream economics, despite the launch of *The Journal of Behavioral Economics* in 1972 (continued as *The Journal of Socio-Economics* since 1991) and such publications as Katona and Morgan (1980), Gilad and Kaish (1986) (but see Hosseini, 2003). For this reason, Sent (2004) calls these lines of research 'old' behavioral economics. (Given contemporary research such as Altman (2006), perhaps it is more

appropriate to call it heterodox rather than old behavioral economics.)

In retrospect, one reason why 'old' behavioral economics never caught on in the mainstream is that it started from the dismissal of the main methodological tenets of mainstream economics, such as positivism, deductivism, static equilibrium analysis, and optimizing models of economic agency (see Hosseini, 2003: 394). In contrast, as we will see below, 'new' behavioral economics has its deep root in BDR, which exploited maximization models such as EUT as experimental paradigms.

Behavioral Decision Research

Ward Edwards was among the first psychologists to notice the relevance of EUT for psychology. He introduced it to psychologists as *behavioral decision theory* (Edwards, 1954, 1961; Edwards et al., 1963), a rational model of individual probability judgment (subjective Bayesianism) and choice under risk. Edwards, the son of an economist, studied psychology at Harvard under the influence of Mosteller, who introduced Edwards to EUT (Phillips and von Winterfeldt, 2007). In 1958, Edwards moved to the psychology department at the University of Michigan, Ann Arbor, a then-rapidly expanding research center in mathematical psychology and decision-making (see Heukelom, 2010). But it was the following younger generation, including his former students at Michigan, who developed a subfield in cognitive psychology called BDR, by demonstrating systematic violations of the predictions of EUT in a series of experiments, and by proposing alternative models of individual judgment and decision-making. Mainstream economic rational choice models such as EUT were crucial for the development of BDR, since these models provided 'clear and crisp' predictions to be experimentally explored (Sent, 2004; Angner and Loewenstein, 2012); the deviations from the predictions could then be exploited to develop alternative models. In particular, two developments in BDR are important for the rise of 'new' behavioral economics.

Preference Reversals and the Construction of Preferences

One of the first systematic violations of EUT was demonstrated by Sarah Lichtenstein (1933 to present) and Paul Slovic (1938 to present), Edwards's former students, then working at the Oregon Research Institute. They conducted a series of experiments on people's risk assessments of hypothetical gambling, and discovered a serious anomaly for EUT called *preference reversal* (Lichtenstein and Slovic, 1971; see also Lindman, 1971), reported essentially the same result). Preference reversal is a phenomenon in which the decision-maker's preference over a pair of lotteries seems to be flipped depending on the method of preference elicitation. For example, when asked to choose one bet from two, many subjects in Lichtenstein and Slovic's experiments chose a low-payoff, high-probability bet (the so-called P bet, e.g., 35/36 chance of winning $4) over a high-payoff, low-probability bet ($ bet, e.g., 11/36 chance of winning $16); but when asked to state how much they were willing to pay, the subjects priced the $ bet higher than the P bet. The subjects seemed to have violated the axiom of transitivity (as their responses suggested they prefer A to B, and B to A at the same time), but the problem was deeper than that since it challenged the *procedural invariance* principle, a fundamental assumption of rational choice that preferences over an identical set of alternatives should not change depending on how you measure them (e.g., letting subjects rate, choose between, or state reserve prices for options). This result was replicated in a field experiment using real gamblers incentivized with high-stake money in the Four Sisters Casino in Las Vegas (Lichtenstein and Slovic, 1973).

Preference reversals caught economists' attention: two Caltech experimental economists challenged this result, with an explicit attempt to make the phenomenon go away, only to find it persisted (Grether and Plott, 1979). This paper was published in *The American Economic Review*, stimulating economists to produce alternative models to EUT that abandon or modify axiom(s) of EUT. In contrast, Slovic and other behavioral decision researchers proposed procedural models in which preferences are constructed in the process of decision-making (see articles collected in Section III of Lichtenstein and Slovic, 2006).

Framing Effects and Prospect Theory

Another series of serious challenges to EUT came from a team of Israeli-American psychologists Amos Tversky (1937–96) and Daniel Kahneman (1934 to present). Tversky completed his PhD at Michigan in 1965 under the supervision of Clyde Coombs (1912–88) and Edwards. Tversky's early research was on both the representational theory of measurement in mathematical psychology and empirical investigation into subjective EUT (Heukelom, 2009: 48). In the late 1960s, Tversky went back to Israel to teach at Hebrew University, where Daniel Kahneman had been establishing himself as a leading researcher in the field of mental effort. Tversky's faith in subjective Bayesianism was 'severely shaken' by conversations with Kahneman (Kahneman, 2003). The first series of their collaborative work thus studied individual probability judgment under uncertainty; how individuals use mental shortcuts called 'heuristics' such as representativeness, availability, and anchoring and adjustment; and how these heuristics lead to 'biases,' i.e., deviations from the subjective Bayesian model, part of subjective EUT. This research program, known as 'heuristics and biases,' was launched with their first collaborative paper (Tversky and Kahneman, 1971), and further developed in their *Science* paper (Tversky and Kahneman, 1974) and other papers collected in Kahneman et al. (1982) and Gilovich et al. (2002).

Another, perhaps even more important program by Tversky and Kahneman comprises a series of experiments that demonstrated *framing effects* (Tversky and Kahneman, 1981, 1986), and *Prospect Theory* (Kahneman and Tversky, 1979) as an alternative to EUT (other important papers are collected in Kahneman and Tversky, 2000). Broadly speaking, framing effects refer to another type of preference reversals, in which an individual's preference over an identical set of alternatives seems to be flipped depending on how they are described, in particular as a gain or loss. Framing effects are as serious an anomaly to EUT as Lichtenstein and Slovic's preference reversals, because they challenged another invariance principle

in rational choice called the *descriptive invariance*, which states that the agent's preferences over an extensionally identical set of alternatives should not be affected by how they are intensionally described. An innovation of Prospect Theory consisted in its introduction of the concept of *reference points* to explain framing effects and other related anomalies *within the framework of utility theory*. One of the central ideas of Prospect Theory is that an individual evaluates gains and losses relative to a certain reference point, not absolute quantities, an application of psychophysics to the perception of money and other goods. Different frames with different reference points shift the perception of alternatives as a gain or loss, and affect individuals' choice. With the assumptions that people are risk-averse toward unlikely loss and likely gain, and risk-seeking toward likely loss and unlikely gain, Prospect Theory explained not only framing effects but also other early problems such as Allais's paradox, and people's simultaneous purchasing of lotteries and insurances that had been discussed earlier by Friedman and Savage (1952) and Markowitz (1952). (For a critical assessment of Prospect Theory and related models of risky choice, see Friedman et al. (2014).)

Tversky and Kahneman's 1979 *Econometrica* paper (Kahneman (2003) recalls: "The choice of venue turned out to be important; the identical paper, published in *Psychological Review*, would likely have had little impact on economics. But our decision was not guided by a wish to influence economics. *Econometrica* just happened to be the journal where the best papers on decision-making to date had been published, and we were aspiring to be in that company.") and their 1981 *Science* paper were hailed as having "altered the intellectual history of economics; they brought the behavioral economics research program into the mainstream" (Laibson and Zeckhauser, cited in Angner and Loewenstein, 2012: 662). This reputation of Prospect Theory is due not only to its empirical success, but also to its unique hybrid nature: on the one hand, it is a psychologically informed cognitive process model in which alternatives are mentally 'edited' as gains and losses before choice; on the other, it is presented as a utility maximization model with a peculiar utility curve, representing different subjective valuations of likely and unlikely outcomes in gain and loss domains. Unlike 'old' behavioral economics and other BDR, Prospect Theory demonstrated an appealing, paradigmatic way of incorporating insights from cognitive psychology into economic models of choice.

'New' Behavioral Economics

The success of Prospect Theory encouraged a number of young economists to challenge the standard models of rational choice. In *Toward a Positive Theory of Consumer Choice* (1980), for example, Richard Thaler (1945 to present) discussed, drawing on Tversky and Kahneman's work, various aspects of consumer behavior (e.g., underweighting of opportunity costs, failure to ignore sunk costs, regret, and self-control) that would become central themes in behavioral economics. Thaler spent the 1984–85 academic year visiting the University of British Columbia to work with Kahneman, who recalls that "That was the year that behavioral economics began" (Poundstone, 2010: chapter 17). Thaler also contributed to the dissemination of empirical findings challenging economic models of choice, and helped mainstream economists to see the relevance of these results, through publishing, in collaboration with psychologists and economists, 'Anomalies' columns in the *Journal of Economic Perspectives*, between 1987 and 1991 (later collected in Thaler, 1992), and 1995–2001 (see Heukelom, 2012: fn. 16).

Two private foundations, the Sloan Foundation and Russell Sage Foundation, also played a key role in developing behavioral economics as a thriving subfield of economics, through financially supporting the behavioral economics program (1984–92), including projects such as nonresidential working groups, the visiting researchers program, and the Russell Sage Foundation Behavioral Economics Books Series (Heukelom, 2012). Eric Wanner (1942 to present), a former Harvard cognitive psychologist, who had a clear goal to apply cognitive science to economics, played a pivotal role as a director of the behavioral economics program at both foundations. Wanner involved Tversky, Kahneman, and Thaler from early on at the preparatory stage of the program. Although Wanner initially understood the program as a development of Simon's behavioral economics that was highly critical about the mainstream neoclassical economics, he quickly adopted several strategies to bring new behavioral economics to the mainstream. For example, he emphasized applications of behavioral insights to the study of economically important domains such as financial markets. Wanner also solicited prominent and promising economists for applications, including Kenneth Arrow (1921 to present), Vernon Smith (1927 to present), George Akerlof (1940 to present), and Robert Shiller (1946 to present) (Heukelom, 2012). (Smith, who shared the 2002 Nobel Prize with Kahneman, however, was critical about the direction of the behavioral economics program by the 1990s; his prize was awarded for a distinct research program called experimental economics.) Simon, one of Wanner's 40 invitees in 1985, criticized Wanner's program for taking "too seriously the premises of contemporary economic methodology that theories ('models') come first and empirical work afterward"; for Simon, the problem was that "mainline economists continue to ignore vast bodies of relevant evidence in their preferred pursuit of armchair model building" (Simon's 1986 letter to Wanner cited in Heukelom (2012)). Wanner and his advisors, however, seem to have been aware that a key to the success of behavioral economics was to accommodate psychological findings *without* giving up economists' way of model building.

The 'Second-Wave' Behavioral Economics

Matthew Rabin (2002: 658) observed the rise of 'second-wave behavioral economics,' which "moves beyond pointing out problems with current economic assumptions, and even beyond articulating alternatives, and on to the task of systematically and formally exploring the alternatives with much the same sensibility and mostly the same methods that economists are familiar with." As examples, he mentions the models of time preferences and social preferences. (In the

domain of risk preferences, Tversky and Kahneman's (1992) Cumulative Prospect Theory can be seen as a 'second-wave' upgrade of their original Prospect Theory.) In the following two subsections, I illustrate these models in turn, and in the last subsection I briefly discuss recent criticisms of these 'second-wave' models.

Modeling Dynamically Inconsistent Preferences

Since important economic behavior such as saving concerns consumption that are to be made over an extended period of time, economic theory needs to explicitly model how consumers value delayed as well as immediate consumptions. Paul Samuelson (1915–2009) proposed the discounted utility model (DUM), which had become the standard model of time discounting (Samuelson, 1937). One of the fundamental assumptions of DUM is that "[d]uring any specified period of time, the individual behaves so as to maximie the sum of all future utilities, they being reduced to comparable magnitudes by suitable time discounting" (p. 156). As a 'suitable time-discounting' function, Samuelson proposed, without any commitment to its empirical or normative plausibility, the following exponentially declining discount function:

$$d(t) = \delta^t \qquad [1]$$

where $0 < \delta < 1$. An exponential discount function is characterized by a *constant discount rate* for all future events. Thaler (1981), however, using a survey method, showed that the per-period discount factor δ declined over time. Later studies have confirmed this result (see Frederick et al., 2002, for a review). Intuitively put, this is because people value the present and future very differently. People obviously value present consumption (at time t) more than future consumption at $t+1$, but an exponential discount function suggests that the discount rate between t and $t+1$ is the same as that between $t+1$ and $t+2$. But since the former case is a comparison between the present event and a future one, while the latter between two future events, the former should show more pronounced discounting. To capture this feature of time discounting, Laibson (1997) adopted a 'quasi-hyperbolic' discount function, which had been used in a model of intergenerational altruism by Phelps and Pollak (1968):

$$d(t) = \beta\delta^t \qquad [2]$$

where $0 < \delta < 1$, and $0 < \beta < 1$. Hyperbolic discount functions imply discount rates that decline as the discounted event is moved further away in time, capturing familiar problems of impulsive behavior and procrastination. Note that hyperbolic discounting generalizes the standard assumption of exponential discounting, i.e., (2) reduces to (1) if $\beta = 1$, while retaining Samuelson's assumption about the existence of a time-additive utility function. Laibson (1997) adopted a discrete, rather than continuous, version of a hyperbolic discount function (hence the 'quasi' qualification), in order to "[mimic] the qualitative property of the hyperbolic discount function, while maintaining most of the analytical tractability of the exponential discount function" (p. 450). This is the kind of 'sensibility' and the methods that economists are familiar with.

Modeling Prosocial Preferences

Another growing domain of research in behavioral economics is the study of prosocial behavior. Although the default assumption in the theory of public goods since Samuelson (1954) had been selfish individuals, viz., that individuals care only about self-interest narrowly defined in terms of own material gains and losses, the field evidence such as successful voluntary provision of public goods and charitable giving prompted economists to propose alternative models of nonselfish preferences that better explain the observations (e.g., Becker, 1974; Sugden, 1984). Experimental economists and psychologists have also tested since 1980s so many different variations of prisoner's dilemma and public goods games that there is now substantial body of evidence against the selfishness assumption (see Ledyard, 1995; Chaudhuri, 2011).

However, the business of modeling prosocial preferences boomed with the inventions of other games from which one can more straightforwardly infer players' beliefs and preferences. The *ultimatum game* (Güth et al., 1982) is a game in which one player (the Proposer) makes a take-it-or-leave-it offer, as a division of a sum of money between herself and another player. If the second player (the Responder) accepts the division, then both players earn the specified amounts. If the Responder rejects it, they both get nothing. The standard prediction (rational play plus selfish preference) is that the Proposer will offer a minimum divisible sum of the money, which will be accepted by the Responder: for the Responder, any positive sum is better than zero (money maximization); since the Proposer knows this, she proposes the smallest amount to maximize her own money. Evidence from experiments shows that Proposers offer on average 30–40% of the money (modal and median offers are 40–50%); and Responders reject small offers below 20% about half the time. These results clearly falsify the standard prediction. Even in the game in which the Responder has no choice but to accept the offer (the *dictator game*, Kahneman et al. (1986)), the Dictator offers on average about 20% of the sum (see Camerer, 2003).

Models of *social preferences* try to accommodate the data across these experimental games, as well as prisoner's dilemma and public goods games. Rabin (1993), employing *psychological game theory*, proposed a model of *reciprocal fairness*, where one player matches another's 'intention,' which is inferred from the payoff structure of the game. For example, a responder in an ultimatum game may act 'mean' (reject) if she thinks the proposer to be 'mean' for offering, say 20%, because he could have offered her 40%, if not 50%. Fehr and Schmidt (1999) offered another model of *inequality aversion*, in which players have a preference for egalitarian distribution of the payoffs. For example, an inequality-averse player may give a substantial portion of the pie to the second player in a dictator game.

Recent Criticisms of the 'Second-Wave' Models

In recent years, these models of 'second-wave' behavioral economics attracted mainly two types of methodological criticism. The first concerns its single-minded modification of functional forms instead of explicitly modeling plausible

psychological *processes* (e.g., Rubinstein, 2003). In particular, social preference theorists' conviction that "[f]or modeling purposes, behaviorally relevant emotions can be captured by appropriate formulations of the utility function" (Camerer and Fehr, 2004: 80) have been challenged on several conceptual and methodological grounds (Heap and Varoufakis, 2004; Guala, 2006; List, 2007). Accordingly, models that draw more directly on cognitive and social psychology have been proposed (e.g., Bicchieri, 2006).

The second type of criticism concerns the specific ways in which behavioral economists interpret the data from experiments. In particular, Ross (2014) criticizes their strategy to identify central tendencies in a small sample and explain them in terms of common psychological dispositions of individuals, or utility functions that represent such tendencies (pp. 156, 233, 250). Ross instead advocates the approach to econometrically estimate the structure of *heterogeneity* in the data-generating processes in the large data set, in order to predict how such heterogeneity respond to policy interventions at the population level (see Andersen et al., 2008).

Conclusion

In this article, I briefly sketched the historical development of behavioral economics, which is nicely summarized as what Camerer and Loewenstein (2004: 7) call a 'recipe' of behavioral economics:

> First, identify normative assumptions or models that are ubiquitously used by economists, such as Bayesian updating, expected utility, and discounted utility. Second, identify anomalies – i.e., demonstrate clear violations of the assumption or model, and painstakingly rule out alternative explanations (such as subjects' confusion or transactions costs). Third, use the anomalies as inspiration to create alternative theories that generalize existing models. A fourth step is to construct economic models of behavior using the behavioral assumptions from the third step, derive fresh implications, and test them.

My narrative has along the way emphasized a key to the academic success of behavioral economics, namely its adoption of standard economic modeling techniques such as utility maximization and equilibrium analysis. But the prominence of behavioral economics might not be as stable as it appears now, for it faces challenges from *both* psychology and economics, as briefly discussed in Section Recent Criticisms of the 'Second-Wave' Models: one the one hand, the psychological critique suggests the limits of modeling *individual psychological processes* using existing economic methods; on the other, the economic (or econometric, to be more specific) critique points to the limits of modeling *aggregate-level data-generating processes* using a single representative functional form. It remains to be seen how behavioral economists will address these distinct challenges, and how their disciplinary identity will be affected as a consequence.

Abstract

Behavioral genetics is concerned with the study of genetic influences on behavior; however, it also tells us about the importance of the environment. Through multiple levels of analyses ranging from quantitative genetic to molecular genetic studies of DNA to epigenetics and gene expression, this field examines the roles of genes and environment on individual differences in an outcome of interest. This report, focused on human behavior, outlines the foundations and future of this growing field.

Behavioral genetics is concerned with the study of genetic influences on behavior. Despite this definition, behavioral genetics also tells us about the importance of the environment. Behavioral genetics encompasses a wide range of levels of analyses, ranging from quantitative genetics to molecular genetic studies of DNA as it relates to behavior. More recently, efforts also include investigation of epigenetics as well as gene expression, described later in this article. Despite this wide range of methodological approaches, the core focus for most behavioral genetic research remains the same: to examine the roles of genes and environment on individual differences in an outcome of interest. For example, why do people differ with regard to personality, addiction, psychopathology, or cognitive ability? The words 'nature' and 'nurture' are often used in the field of behavioral genetics. The history of the nature versus nurture debate is beyond the scope of this article; however, the words nature and nurture will be used throughout as broad categories representing genetic and environmental influences, respectively.

Gregor Mendel (1822–84) is considered the father of heredity. Mendel studied inheritance in pea plants in the garden of his monastery in what is now known as the Czech Republic. On the basis of his many experiments, Mendel concluded that there are two 'elements' of heredity for each trait in each individual, and that these two elements separate, or segregate, during reproduction (Plomin et al., 2013). These elements are now known as genes. In the study of heredity, the focus is on genes that have different forms (called alleles) across individuals, animals, plants, or other model organisms. Each individual's combination of genes is called their genotype. The observed behavior or trait is called a phenotype. The fundamental issue in behavioral genetics is the extent to which differences in genotype account for differences in phenotype (or the observed differences among individuals).

Quantitative genetics – used, for example, in twin and adoption studies (described later) – rely on Mendel's laws of heredity but do not require knowledge of the biological basis of heredity. Molecular genetics, in contrast, looks at specific variation in individual genes or across the genome and, as described later, the epigenome and transcriptome. The human genome consists of about three billion base pairs, and 99.9% of this DNA sequence is identical for all human individuals. This leaves about three million base pairs that vary among individuals. There is no single human genome. In fact, we each have a different genome, with the exception of identical twins. It is the variation in the genome that can tell us, in part, about the origin, or etiology, of diseases and disorders. These variations are the focus of behavioral genetics.

More specifically, the DNA sequence defines our genes. Genes code for sequences of amino acids that form the thousands of proteins of which organisms are made. Proteins create the skeletal system, muscles, the endocrine system, the immune system, the digestive system, and most important for behavior, the nervous system. Genes do not code for behavior directly, but DNA variations that create differences in the abundance or function of the proteins that comprise these physiological systems can affect behavior (Plomin et al., 2013). It is important to note that while it is the variation in the genome that is of interest to the field of human behavioral genetics, many of the conserved genetic regions that are most important from an evolutionary perspective are nonvarying. In humans, it is not possible to study the effects of nonvarying genes; however, in animal models, differences in such genes can be created by 'knocking out 'the genes 'functioning (Plomin, 2001; Plomin and Crabbe, 2000). There is an ever-growing literature capitalizing on the power that animal models bring to behavioral genetic questions. This article, however, is limited to research on human behavior. Behavioral genetics uses methods of both quantitative and molecular genetics to study behavior.

Quantitative Genetics

Quantitative genetics offers a powerful theory as well as various methods for investigating the genetic and environmental etiology of any measurable phenotype or outcome. Most behavioral, psychological, or psychiatric traits are much more complex than single-gene disorders such as Huntington disease. Such complex phenotypes are influenced by multiple genes and likely multiple environmental factors. Because behavioral genetics is concerned with the study of individual differences, or detecting the factors that make individuals in a population different from one another, the first step is

typically to try to gauge the relative importance of genetic and environmental factors that cause individual differences. Quantitative genetics does this without specifying what the specific genes or environmental factors are. (It is now possible to identify what those specific genes are by using molecular genetic methods, which are briefly outlined later in this article.) Rather than using genetically defined populations, such as inbred mouse strains (strains that have been developed via brother–sister matings to result in nearly genetically identical individuals), or manipulating environments experimentally, human quantitative genetics focuses on naturally occurring genetic and environmental variation.

Although an outline of the model that forms the basis of quantitative genetics work is beyond the scope of this article, it is important to understand that by incorporating the basic laws of heredity and the expected genetic relationships among different kinds of relatives, quantitative genetics provides methods that focus on family data or variations of the family model. Most behavioral genetic analysis contrasts phenotypic similarity between related individuals with their genetic similarity. If individuals who are more closely related genetically also tend to be more similar on a measured trait, there is a suggestion for that trait being heritable, or influenced by genetic factors. Twin and adoption models are widely used for their ability to examine genetic and environmental influences on complex traits, like behavioral and psychological outcomes.

In genetic research, the word 'environment' refers to everything that is nongenetic. This is a much broader definition than is typically encountered in social and behavioral science. More specifically, environment denotes all nonheritable factors, including possible biological events such as early childhood illness, not just psychosocial factors that are usually considered in the behavioral and social sciences (Plomin, 2001). The environment impacts the development of behavioral and psychiatric disorders and the environment influences genetics as well (Li, 2010). There is a clear need to carefully measure the environment and to be mindful that many environmental measures show genetic influence (Kendler and Baker, 2007). Thus, genetically sensitive designs that incorporate and investigate interactions and correlations between genes and environments are important to the field moving forward (Knopik, 2011).

The Adoption Design

Family resemblance can be due to either genes or environment, or some combination of both. Adoption designs provide a way to disentangle these genetic and environmental sources of familial resemblance. Adoption creates genetically related individuals who do not share a common family environment because they were adopted apart, such as a birth mother and her biological child who was placed into an adoptive family at birth. Adoption also creates adopted-together family members who share a common family environment but are not genetically related, such as the adoptive mother and the adopted child. Adoption studies often yield evidence for genetic influence on behavioral traits, although results depend on the trait examined and the age of the adopted child (Plomin et al., 2013).

The first adoption study of schizophrenia, reported by Heston in 1966, was highly influential. At that time, it was hypothesized that early life and family experiences, such as poor parenting, caused schizophrenia. The Heston adoption study (as well as many other subsequent adoption studies) showed that the risk for developing schizophrenia was similar in adopted offspring of schizophrenic birth mothers and in children reared by their schizophrenic birth parents. These findings suggested not only that the rearing environment had little effect, but also that genetics makes a major contribution to this disorder.

Adoption designs do, however, have certain assumptions and limitations. First, there is question about the representativeness of adoption samples. That is, if biological parents, adoptive parents, or adopted children are not representative of the population, then this could affect the generalizability of results from adoption designs. Second, there is question of the prenatal environment. Resemblance between the birth mother and the adopted child might reflect prenatal environmental influences rather than, or in addition to, genetic influences. Third, due to an increase in 'open' adoptions, where birth parents and the adoptive parents know each other or share information, there is a concern about the extent to which the adopted child's rearing environment is truly independent of genetic influences from the birth parents. Finally, there is also the possibility that adopted children might be selectively placed with adoptive parents matched to the birth parents. Thus, there might be an issue with correlated environments. Many of these issues can be examined empirically (Plomin et al., 2013) and have been found to differentially influence different outcomes.

The Twin Design

The majority of quantitative genetic studies have focused on twins. Genetically, fraternal (dizygotic, or DZ) pairs, who develop from separately fertilized eggs, are no more alike than siblings who share, on average, 50% of their genetic material. Identical (monozygotic, or MZ) pairs are genetically identical because they came from the same fertilized egg. If genetic factors are important for a trait, these genetically identical pairs of individuals should be more similar than DZ twins who are only 50% similar genetically. If environmental factors are important for a trait, DZ twins should be as similar for the behavior as are MZ twins. Following the example of schizophrenia, twin studies show that genetics are an important contribution to familial resemblance for schizophrenia (Sullivan et al., 2003; Cardno et al., 2012).

The twin method has a different set of assumptions and potential limitations. First, it is possible that greater similarity in MZ twins is caused by environment rather than genetics because the twins are the same age, the same sex, and look alike. The *equal environments assumption* assumes that environmentally caused similarity is roughly the same for both MZ and DZ twins reared together. This assumption has been tested and appears reasonable for most traits (e.g., Bouchard and Propping, 1993; Derks et al., 2006). Second, as with the adoption design, generalizability is an issue for the twin method. Although twins are often born premature and may experience delays in language development, among other

things, the statistical distributions for most behaviors for twins and nontwins are generally similar, which suggests that twins are reasonably representative of nontwin populations (e.g., Robbers et al., 2011).

Estimating Genetic Influences on Behavior

Complex phenotypes, such as behavioral and psychological outcomes, are influenced by multiple genes and likely multiple environmental factors. The first step in quantitative genetics is typically to try to gauge the relative importance of genetic and environmental factors that cause individual differences. The next question might be to determine *how much* genetics contributes to a trait. This can also be described as the proportion of the phenotypic variance that is accounted for by genetic influences, or heritability. Heritability can be estimated from the phenotypic correlations between relatives. For example, in the adoption design, if the correlation for 'genetic' (adopted apart, such as birth mother and her biological child who was placed in an adoptive family at birth) relatives is zero, then heritability is suggested to be zero. If identical and fraternal twin correlations are the same, heritability is zero. If identical twins correlate 1.0 and fraternal twins correlate 0.50, a heritability of 100% is implied (Plomin et al., 2013). A rough estimate of heritability can be obtained by doubling the difference between MZ and DZ twin correlations.

Unfortunately, the results of quantitative genetic studies are often misunderstood and thus misinterpreted. It cannot be reiterated enough that heritability is the genetic contribution to individual differences (variance), not to the phenotype of a single individual. Heritability is a statistic that describes the contribution of genetic differences to the observed differences among individuals in a particular population at a particular time. In different populations or at different times, environmental or genetic influences may differ, and thus heritability estimates in such populations might differ (e.g., differences in obesity attributable to Western obesogenic environments might lead to different heritability estimates in different eras in US history and might result in very different heritability estimates for obesity in cultures with non-Western diets). Moreover, the causes of individual differences within a group have no implication to the cause of average differences between groups (e.g., men and women). Heritability refers to the genetic contribution to differences among individuals within a group. Heritability also does not imply genetic determinism. That is, just because a trait is heritable, or shows genetic influences, does not mean that nothing can be done to change it. Considering a behavioral example, if reading disability is 50% heritable, that does not mean that if one or more of your parents has a reading difficulty that you are 50% at risk. Rather, it means that of the reading scores available for a particular population at a particular time, 50% of the variance of those scores can be attributed to genetic influences. If we also consider height, which has a heritability of 90%, this does not mean you grew to 90% of your height for genetic reasons and the other inches are due to your environment. That said, even for a highly heritable trait such as height, changes in the environment could make a big difference.

A new direction in quantitative genetics uses measured genotypes to directly estimate genetic influences (rather than indirectly via comparison of correlations between sets of relatives, such as MZ and DZ twin pairs). This technique is called genome-wide complex trait analysis (GCTA; Yang et al., 2011). This method compares pairwise genetic similarity across DNA markers called single nucleotide polymorphisms (SNPs) for each pair of unrelated individuals. SNPs involve the mutation of a single nucleotide and are by far the most common type of DNA polymorphism. The GCTA method makes it possible to estimate heritability directly from DNA markers in a manner that is analogous to more traditional quantitative genetic methods, such as the twin design. More specifically, GCTA can estimate the total amount of phenotypic variance captured by all SNPs on the current generation of commercial genotyping arrays (Yang et al., 2011). This method comes with its own set of limitations; however, the value is that is does not require special samples such as twins or adoptees. Essentially, in any large sample with genotypes on hundreds of thousands of SNPs, GCTA can be used to estimate genetic influences for behavioral traits, such as the personality dimensions of neuroticism and extraversion (Vinkhuyzen et al., 2012) as well as the genetic overlap between traits, such as longitudinal measures of cognitive ability from childhood to old age (Deary et al., 2012).

Behavioral genetics not only gives us an idea of whether and how much genetics contributes to a trait, it also tells us about the environment. In fact, behavioral and psychiatric genetics research provides the best possible evidence for the importance of the environment. That is, if the heritability of a certain trait is 50%, the remaining 50% is due to the environment. For complex genetic traits such as those behavioral phenotypes described here, genes do not equal destiny.

Identifying Genes and the Pathways between Genes and Behavior

Quantitative genetics continues to identify *whether* there are genetic influences on behavioral traits, as well as *how much* those genetic factors account for. However, heritability estimates tell us nothing about specific genes. Since the 1980s, quantitative genetics and molecular genetics have been working together to identify specific genes responsible for genetic influence on behavior. These are exciting times because the identification of specific genes, or sets of genes, can provide information that will guide the exploration of pathways between genes and behavior.

For complex human behaviors, genetic influences are likely comprised of multiple genes of varying but small effects rather than a single gene or a few genes of large effect. The goal is to find some, but likely not all, of the genes that make contributions of varying effect size to the variance of a trait. There are multiple molecular genetic strategies that aid in this goal, for example: (1) whole-genome sequencing (Lander, 2011) detects most DNA polymorphisms across the genome and will enable researchers to look at both coding and noncoding parts of the genome in an attempt to capture genetic effects on behavior, but this remains a very expensive strategy; (2) exome

sequencing, or sequencing the 2% of the genome that contains protein-coding information (Bamshad et al., 2011), is becoming widely used as the cost is less prohibitive than whole-genome sequencing; and (3) microarrays continue to be used to genotype millions of SNPs on a chip, and have allowed for genome-wide association to dominate the attempts to identify genes in recent years.

Genome-wide association results have been less promising than once expected in that they have yielded genes accounting for much less of the genetic variance than suggested by heritability estimates. For most traits, the associated SNPs from genome-wide association studies only explain a small fraction of the heritability, leading to the 'missing heritability' problem (Maher, 2008). There are multiple explanations for this missing heritability (see Maher, 2008; Manolio et al., 2009), including the possibility that the heritability is not missing but has not previously been detected because the individual effects are too small to pass stringent significance tests in genome-wide association analyses (Yang et al., 2011). Using attention-deficit hyperactivity disorder (ADHD) as an example, how can we as a field reconcile the fact that the variance explained by successfully located genetic variants for ADHD account for only 1% of the variance (Franke et al., 2009), while heritability estimates from twin and family studies suggest approximately 80% (Knopik et al., 2005)? This concept of 'missing heritability,' that is, the presumed inconsistency between heritability estimates and the ability to explain this genetic variance with genetic markers (Maher, 2008), is nontrivial. New technologies, such as exome or whole-genome sequencing, may begin to shed light on this issue. In addition, in the interim it is possible to aggregate the small effects of many DNA variants associated with a trait (Wray et al., 2008). Such polygenic composites have been called polygenic susceptibility scores (Pharoah et al., 2002), genomic profiles (Khoury et al., 2004), SNP sets (Harlaar et al., 2005), genetic risk scores (Morrison et al., 2007), and aggregate risk scores (Purcell et al., 2009). With the advent of rare variant genotyping, new approaches combine the effects of rare and common variants, including variants that are risk inducing as well as protective (Neale et al., 2011). The missing heritability problem needs to be remedied or at least relieved before the potential of DNA can be actualized in behavioral and psychiatric genetic research (Plomin, 2013). Once we find genes associated with behavior, the next step is to understand the pathways between genes and behavior, or the mechanisms by which genes affect behavior.

Genetic information is transcribed from DNA into messenger RNA and then translated into protein. DNA is the same at all ages, and at all times (Plomin et al., 2013). RNA, on the other hand, degrades quickly and is tissue-specific, age-specific, and state- specific. RNA also regulates transcription and translation of protein-coding DNA. Epigenetic mechanisms are relevant to gene expression in that epigenetic changes do not alter the DNA sequence itself but do affect certain mechanisms of gene expression (Bird, 2007). The epigenome can be thought of as molecular material that sits on top, or outside, of the genome. Epigenetic marks, such as methylation or histone modification, can tell your genes to switch on or off (or gene expression). Thus, it may be through epigenetic marks that environmental factors such as diet, stress, and prenatal nutrition can influence gene expression from one cell to another (Zhang and Meaney, 2010; Knopik et al., 2012; Maccani and Knopik, 2012). Just as in the case of DNA, microarrays can be used to assess the degree of expression of all genes in the genome (the transcriptome) as well as DNA methylation of all coding genes in the genome (the methylome). In addition to the methylome, other forms of epigenetic characterization, such as noncoding RNA and histone modification, comprise the epigenome. The importance of these techniques for behavioral genetics lies in the fact that the epigenome and the transcriptome are the first steps in the correlation between genes and behavior.

Genetics in the Behavioral Sciences

Schizophrenia has been used as an example in both the adoption and the twin design sections earlier in the article. In fact, schizophrenia is the most highly studied area in behavioral genetic research on psychopathology. Other areas about which the most is known are cognitive abilities and disabilities, mood and anxiety disorders, autism, ADHD, personality, and substance use. Health psychology, aging, and evolutionary psychology are also beginning to see an upswing in genetically informed research. Moderate genetic influences are found for most behavioral outcomes that have been studied (Plomin et al., 2013). In general, there is a fairly balanced view that accepts the role of nature as well as nurture for many behavioral disorders. Researchers are also making progress in identifying specific genes.

Some of the most far-reaching genetic findings concern genetic comorbidity. For example, when considering psychopathology, people with one disorder have about a 50% chance of having more than one disorder in a 12-month period (Kessler et al., 2005). Behavioral genetics allows us to ask whether there are really disorders that co-occur or whether those comorbidities are seen simply as a function of the current diagnostic systems that tend to be based on phenotypic description rather than cause. In essence, behavioral genetics allows the questions of whether genes that affect one trait also affect another trait. For example, there is genetic overlap between major depressive disorder and bipolar disorder as well as the possibility of genetic overlap between bipolar disorder and schizophrenia. There is also genetic overlap between anxiety and depression, so much so that they are largely the same disorder from a genetics perspective (Kendler et al., 1992; Middeldorp et al., 2005).

Behavioral genetic human research has maintained a strong focus on the areas of behavioral and social sciences that have historically been interested in individual differences. These have been touched on at points throughout this article and include psychopathology, developmental psychopathology, cognitive ability and disability, personality, and substance use. There are certainly other areas of the social and behavioral sciences that have historically focused on the behavior of groups – these areas can be considered a rich area for behavioral genetics. This includes areas of study such as relationships, self-esteem, attitudes, and behavioral economics. For example, to what extent do genetic influences on parents and offspring contribute to relationships, especially the attachment

between infant and caregiver, or empathic emotional responses? To what extent do genetic factors influence the types of friends that we select (or who select us)? How does genetics influence mate selection or relationship quality? A rapidly growing area is also focused on political psychology, the study of political attitudes and behaviors (Hatemi and McDermot, 2011). Recent efforts also show promise in areas of behavioral economics, such as investor behavior (Barnea et al., 2010), financial decision making (Cesarini et al., 2010), and economic risk-taking (Le et al., 2010; Zhong et al., 2009; Zyphur et al., 2009). The field is moving quickly toward molecular genetic research (Beauchamp et al., 2011; Koellinger et al., 2010).

Behavioral genetics is moving beyond psychology and psychiatry into the fields of economics, neuroimaging, and evolutionary psychology. The questions of *whether* and *how much* genetics influences traits will move forward to begin to answer the question of *how* – that is, determining the mechanisms by which genes have their effects (Plomin et al., 2013). In order to answer questions about how genes influence behavior, gene identification efforts need to find specific genes responsible for the widespread influence on behavior. The pace at which information about genetic and epigenetic modification is being produced has created a strain on our available analytic tools when we try to consider the impact or significance of this genetic information. This poses a significant challenge to the field as far as integrating the effects of these individual differences to better understand the biological basis of behavior (Knopik, 2011). In many respects, the grandest implication for science is that DNA will serve as an integrating force across diverse disciplines (Plomin, 2001; Plomin et al., 2013). Just as molecular genetics might lead to personalized genomics, so too is the possibility that genetic findings can be used to research interventions that might prevent a disorder – a direction that behavioral scientists need to be ready to take.

As more genetic data becomes available, it is critical that behavioral and social scientists be prepared to use this information in their research. In fact, some funding agencies are highlighting the importance of considering biological influences, including genetics, in human behavioral research. As specific genes are implicated in behavioral and psychological disorders, social and behavioral scientists should participate in discussions (and inform their students) about the ethical concerns surrounding these types of findings (Plomin, 2001). There is a fear that the results will be used to justify social inequality, to select individuals for education or employment, or to enable parents to pick and choose among pregnancies for the most genetically desirable fetus. More recently, confidentiality concerns have been raised over the ability to identify individuals based solely on their genetic sequence. Many of these concerns stem from misunderstandings of how genes (and the environment) affect complex traits (Rutter and Plomin, 1997). Behavioral genetics has clearly demonstrated that both genes and the environment are important. Thus, behavioral and social scientists need to be informed and prepared to consider both nature and nurture when considering behavior.

Abstract

Behavioral inhibition (BI) refers broadly to a temperament trait of avoiding interaction with novel stimuli because such stimuli provoke anxiety or distress. *Social withdrawal* (SW) is a related construct that refers more specifically to a tendency to avoid interaction with people. Research on these behaviors has flourished over the past 30 years. Such research has demonstrated that biological, cognitive, and social factors contribute in shaping children's BI and SW, and mutually influence the developmental outcomes of these behaviors. Recent research has also shed important light on cultural variability in the social and psychological implications of these behaviors.

The study of children's behavioral inhibition (BI) and social withdrawal (SW) has flourished over the past 30 years, and research over the past decade has shed important light on the social and psychological implications of these behaviors across cultural contexts. BI refers broadly to a temperament trait of avoiding interaction with novel stimuli – including objects, places, and people – because such stimuli provoke anxiety or distress (Fox et al., 2005; Kagan, 1997). Such behavior is found in roughly 10–20% of infants, although the prevalence of such behavior varies across cultures (Kagan, 1997; Chen and French, 2008). Through the 1980s and the 1990s, Jerome Kagan and his colleagues pioneered work on the development and physiological correlates of BI during infancy and early childhood. Meanwhile, the laboratories of Kenneth Rubin, Mary Rothbart, and Jens Asendorpf explored behaviors theoretically linked to BI – SW and *shyness* – which, in contrast to BI, refer more specifically to a tendency to inhibit interactions with people. These research groups focused particularly on the development of SW and shyness during early childhood and identified factors that influence and are influenced by their development. The works of Kagan, Rothbart, Rubin, and Asendorpf, and of their colleagues and students, have had a lasting and profound influence on the field.

Throughout the literature, the terms 'social withdrawal' and 'shyness' have often been used interchangeably, and different researchers have used these terms to refer to different constructs. Recently, theorists have conceptualized SW as a category of behaviors, encompassing several distinct subtypes of withdrawal, one of which is *shyness* (Asendorpf, 1990; Coplan and Rubin, 2010). The following section describes these subtypes. Next, common measures of BI and SW are described. Subsequent sections review biological, cognitive, and social correlates of BI and SW, and describe how the development of BI and SW can be credited to transactional processes among these factors. Importantly, the social evaluation and developmental outcomes of BI and SW differ depending on proximal family and peer contexts as well as broader sociocultural contexts (Chen and French, 2008; Chen et al., 2011). Thus, throughout this article, important, recent research is highlighted, which documents the development and consequences of these behaviors across cultures. The article concludes with an outlook on future directions in the field.

Subtypes of SW

Various subtypes of SW have been identified, each with different causes, correlates, and outcomes. Broadly, subtypes of SW can be categorized along two dimensions – a motivation to approach and a motivation to avoid (Asendorpf, 1990). The term *shyness* has been used to refer to a form of SW characterized by anxiety or self-consciousness in novel social situations, especially situations in which one believes he or she is being evaluated (Asendorpf, 1990; Coplan et al., 2013). Shy children often exhibit *reticent* behavior – watching others interact from the periphery but not directly engaging in social interaction (Coplan et al., 2013). These children may loom near or play beside other children, but tend to not initiate interaction with unfamiliar people and are wary when approached by unfamiliar others. Thus, these children are often described as experiencing an *approach–avoidance conflict* – they want to interact with others, but remove themselves from direct involvement because of the anxiety or distress that social situations provoke.

Socially avoidant children tend to experience extreme fear and anxiety in the face of social interaction and thus have an especially strong avoidance motivation (Asendorpf, 1990; Coplan et al., 2013). Unlike shy children, socially avoidant children have a low approach motivation and less often demonstrate reticent behavior. Their aversion to social interaction leads some socially avoidant children to behave aggressively and impulsively in social situations, and because of their disruptive behavior and negative affect, these children are at higher risk for peer rejection. *Unsociable* or *socially disinterested* children prefer to play alone, but are not particularly anxious or socially disruptive, and are comfortable interacting with others if others initiate the interactions (Asendorpf, 1990; Coplan et al., 2013). Shy children are often attentive of others' social interactions, whereas unsociable children are more focused on objects,

such as toys. Thus, these children can be described as having neither a strong motivation to approach nor a strong motivation to avoid social situations.

SW traditionally refers to children's own (internal) motivation to disengage from direct social involvement. This should be distinguished from *active isolation* (also referred to as *active withdrawal*), which describes social isolation resulting from peer rejection (Asendorpf, 1990; Harrist et al., 1997; Rubin et al., 2009). Although active isolation does not necessarily reflect an individual's motivation to socially disengage, SW – especially SW characterized by high levels of negative affect and socially disruptive behavior – may eventually lead to peer rejection and thus active isolation (Coplan and Rubin, 2010; Rubin et al., 2009).

In the following sections, the term 'social withdrawal' will be used to refer generally to removal of oneself from social interaction, for one reason or another. When the empirical literature explicitly indicates which specific subtypes of SW were examined (e.g., shyness), those subtypes are noted.

Measures of BI and SW

Researchers use a variety of methods to measure BI and SW (Coplan and Rubin, 2010; Rubin et al., 2009). These methods include questionnaires on which parents or teachers rate the frequency or magnitude of children's behavior along several dimensions, including BI or SW. Parents' and teachers' evaluations have the advantage that they reflect children's behavior across a wide time span (e.g., a year in the classroom, or a lifetime) and, especially in the case of parent questionnaires, across a variety of contexts (e.g., at home, in public). Yet, such questionnaires are subject to biases; parents especially may rate their children more positively and more consistent with social norms. Researchers have additionally used peer ratings, whereby children in a classroom identify which of their peers they consider to be shy, friendly, aggressive, and so forth. Both teacher and peer evaluations may be less biased than parent ratings, but are limited in that only classroom behavior is typically considered in the evaluations.

Researchers also directly observe children's behavior in their homes, with peers in their classrooms, or with other children and adults in research laboratories. One of the most widely used measures of BI, developed by Kagan and colleagues, involves having toddlers or preschoolers and their caregivers in a room with novel stimuli (e.g., toys, people); investigators record children's reactions – their fear toward, approach toward, and interaction with the novel stimuli and their tendency to seek their caregivers for comfort. These measures are more objective than parent ratings, but are limited in that children's behavior is often observed across a narrow time span and within a limited context (e.g., an hour in the laboratory). Recently, self-report measures have been used to gauge SW among older children; these measures have the potential to more fully capture the personal motivations behind individuals' SW, but are subject to self-report biases (e.g., to portray oneself positively). Studies that have used several of these methods have revealed modest to strong correlations among measures (Rubin et al., 2009). Importantly, such studies have also identified that the measured inhibition varies depending on the context in which it is assessed and depending on who performs the evaluations.

Development of BI and SW: A Transactional Process

Developmental precursors to BI and SW can be found in early infancy. Reactivity – one's physiological and behavioral response to stimulation – is a strong predictor of BI and SW (Kagan, 1997; Rothbart et al., 2011). Kagan and colleagues found that more reactive 4-month-olds in the United States – that is, those who moved and cried more when they were stimulated by toys, faces, and voices – demonstrated greater fear toward unfamiliar events at the age of 1 and 2 years, when compared to nonreactive children (Kagan, 1997; Kagan and Snidman, 1991). Children who had been classified as fearful/inhibited toddlers talked and smiled much less than their peers at 4 years; at this age, many of these children would be considered socially withdrawn. Moreover, inhibition during infancy and early childhood is predictive of SW in late childhood, adolescence, and early adulthood; and this has been found in a variety of cultures (Fox et al., 2005; Rubin et al., 2009). Extremely withdrawn children are particularly likely to demonstrate a stable pattern of SW across development (Rubin et al., 2009). However, only a small portion of children maintain an extreme form of a reactive/inhibited profile across development; instead, it is more common for children to regress toward the mean – for example, for extremely reactive infants to develop into somewhat timid children (Kagan, 1997). Thus, early BI is predictive of later SW, and SW in early childhood is predictive of SW throughout development. Moreover, SW is relatively stable across contexts – children with extreme SW in particular tend to exhibit such behavior toward their peers in a variety of settings (e.g., at home, in school, at community events).

Findings that developmental precursors to BI and SW are present very early in life, findings that inhibited individuals often remain so throughout development, and genetic studies demonstrating the heritability of inhibited behavior all point to the strong biological bases of BI and SW (Fox et al., 2005; Kagan, 1997; Kagan and Snidman, 1991). However, relations between biology and behavior are not straightforward – early cognitive and behavioral dispositions interact to predict SW. For example, among US children, Pérez-Edgar et al. (2011) found an association between early BI (at 2–3 years) and later SW (at 5 years) only among children who paid the greatest attention to threatening stimuli – those who stared longest at angry faces during a laboratory task.

Children's environments, including the broader culture and the more proximate family and peer contexts, also shape the development of inhibited behavior as well as the psychosocial consequences of such behavior (Chen and French, 2008; Chen et al., 2011; Oh et al., 2008). Indeed, recent research has demonstrated that biological, cognitive, and environmental factors interact to shape children's BI and SW and mutually influence the developmental outcomes of these behaviors. Thus, the development of these behaviors and their outcomes can best be described as functions of complex transactions between internal factors (biology, cognition) and

environmental factors (other people) – infants' biologically driven reaction to novel entities influences how other people respond to infants, which in turn shapes children's biological, emotional, and cognitive development, which then further shapes children's environments (Rubin et al., 2009). This reciprocal, transactional process continues throughout the life span. Thus, even though there is moderate stability in BI and SW across development (Kagan, 1997; Rubin et al., 2002), environmental and cognitive factors influence the prevalence and outcomes of these behaviors.

Biological Correlates of BI and SW

Inhibited behavior is associated with several neurophysiological systems and processes, including the limbic system, autonomic nervous system (ANS), hypothalamic-pituitary-adrenal (HPA) axis, and prefrontal cortex (PFC). The amygdala is a medial temporal lobe structure involved in the limbic system. This structure plays an important role in processing emotional sensory information, including others' facial expressions, especially negative expressions, such as fear, and auditory stimuli associated with danger or anger. How the amygdala processes potentially threatening stimuli influences regulation of both the ANS – via the amygdala's projections to the hypothalamus – and the HPA axis; this has implications for BI and SW (Fox et al., 2005; Kagan, 1997; Lopez et al., 2004).

The ANS is composed of the sympathetic nervous system (which regulates 'flight-or-flight' responses to threat) and the parasympathetic nervous system (which calms the body down following a threat). The high reactivity typical of shy individuals might be partly attributable to overactivation of the sympathetic nervous system or to poorer functioning of the parasympathetic nervous system (Kagan, 1997). Indeed, studies have demonstrated that behaviorally inhibited toddlers and young children tend to have higher resting heart rates – an indicator of ANS activation – and resting heart rate is a predictor of SW in the preschool years (Fox et al., 2005; Kagan, 1997).

The HPA axis is also responsible for regulating humans' response to stress. When an individual encounters stressors, the HPA axis produces hormones, which activate other neural systems, eventually leading to the release of cortisol by the adrenal glands; cortisol, in turn, regulates the physiological response to the stressors. Thus, the level of cortisol found in saliva, urine, or blood is commonly used as a marker of individuals' level of physiological stress. Many studies have found a positive association between children's daily resting cortisol levels and SW (Lopez et al., 2004). For example, Blair et al. (2004) found that children who were rated as having both high approach and high withdrawal motivations (i.e., a typical characterization of shy children caught in an approach–avoidance conflict) had both higher resting heart rates and higher cortisol levels. One prominent hypothesis is that some withdrawn children experience consistently high levels of stress (reflected in their heart rates and cortisol), leaving them with a relatively low threshold for additional social stress. Thus, rather than socially engaging, these children withdraw from social situations in an attempt to avoid additional stress (Fox et al., 2005; Lopez et al., 2004).

The PFC is involved in a host of cognitive processes. Critical to SW is the role of the PFC in regulating emotion and behavior (Fox et al., 2005; Lopez et al., 2004). Generally, the left regions of the PFC are involved in processing positive emotions and approach-oriented emotional responses, whereas the right regions are involved in processing negative emotions and withdrawal-oriented emotional responses. Cerebral asymmetry in processing emotions, specifically more marked activation of the right hemisphere relative to the left hemisphere (i.e., 'right frontal asymmetry'), is linked to BI and SW. Inhibited infants, preschoolers, and older children show greater right frontal asymmetry, whereas outgoing infants and children show greater left frontal asymmetry (Fox et al., 2005). Lopez et al. (2004) have proposed that right frontal asymmetry might reduce signals that the PFC sends to decrease activation of the amygdala, which would in turn maintain HPA axis activation. The PFC also plays a role in regulating individuals' behavioral responses to physiological and environmental stimulation and thus could directly influence whether and how individuals' SW manifests (Rothbart et al., 2011).

BI and SW in Social Contexts

Cultural Influences on BI and SW

Different behaviors are favored in different cultural contexts, and social expectations about shy or reserved behavior vary markedly between cultures (Chen and French, 2008). These social expectations influence the prevalence of BI and SW, the ways inhibited individuals are treated by others, and their psychological health.

Cultural values influence people's attitudes toward social behavior. Broadly, many Western societies, such as the United States and Canada, highly value individualist behaviors including autonomy and assertiveness, while many East Asian and Latin American societies place greater emphasis on collectivist behaviors, such as self-control and actions that facilitate group harmony (Triandis, 1995). Individualist and collectivist values coexist in most cultures, but the relative balance of these values within cultures can help us understand the development, prevalence, evaluation, and adjustment outcomes of BI and SW across cultures.

Cultural values can influence the development and consequences of children's BI and SW through several pathways. First, cultural values shape parents' socialization goals for their children. Second, children adopt existing cultural norms for social behavior and apply them when they respond to peers' SW (Chen and French, 2008). Thus, the prevalence of BI and SW will vary depending on cultural values, as parents and peers either facilitate or discourage their development. For example, during laboratory free play sessions, toddlers in more collectivist East Asian countries, such as Korea and China, show more inhibited behavior than toddlers in more individualist cultures, such as Italy and Australia (Rubin et al., 2009).

BI and SW in Parent–Child Relationships

The quality of the parent–child attachment relationship is strongly associated with the development of BI and SW. In the

United States, infants with insecure attachments to their primary caregivers are more likely to exhibit BI during toddlerhood and are more likely to exhibit SW in preschool and school age (Hastings et al., 2010). Similarly, urban Chinese school-aged children's self-reported insecure attachment with their caregivers is associated with SW, whereas secure attachment is associated with greater social initiative (Chen, 2012). These findings suggest that feelings of mistrust and fear derived from an early insecure attachment might influence the development of SW. Children's SW can also affect the parent–child attachment relationship. For example, inhibited children's high arousal and wariness tend to elicit extremely solicitous (i.e., physically close and controlling) parenting, which may contribute to an insecure attachment relationship.

Mothers' affect, personalities, and parenting styles are closely linked to shy children's socioemotional adjustment. For instance, mothers' negative affect and neuroticism are linked to increased internalizing problems and social dissatisfaction among shy preschoolers. Parents with neuroticism are more likely to adopt an overprotective parenting style especially when their children are shy because such parents are more likely to see their children's behavior as problematic and in need of correcting (Rubin et al., 2009). Overprotective parenting can discourage independence and reduce opportunities for children to develop coping skills and problem-solving strategies, which can be especially problematic for withdrawn children. Overprotective parenting is predictive of inhibited preschoolers' shyness and reticence in the United States and Korea, and is predictive of peer difficulties and internalizing problems among Canadian kindergarteners (Hastings et al., 2010; Rubin et al., 2009). Other studies have found that parents' perceptions of their toddlers' shyness predicts overprotective parenting in the following years. Collectively, the findings just reviewed indicate that there are bidirectional relations between children's shyness and parental behavior across development (Rubin et al., 2009).

Certain qualities of parents and parenting styles can facilitate the positive development of shy children. For example, Canadian mothers' agreeableness – their competence in regulating their own emotions – is associated with fewer internalizing problems and peer difficulties among shy kindergarteners (Rubin et al., 2009). Agreeable mothers tend to display higher parental warmth and responsiveness and are able to assist in their shy children's emotion regulation; such parenting mitigates the links between shyness and negative adjustment outcomes. Thus, parental reactions to children's early dispositions influence children's developmental trajectory to SW and influence adjustment outcomes for withdrawn children.

How parents evaluate and respond to children's SW varies across cultures. In general, parents in individualist cultures tend to view SW negatively and associate such behavior with submissiveness, dependency, and timidity (Rubin et al., 2009), whereas parents in collectivist cultures evaluate SW more positively as a sign of respectfulness and self-control (Chen and French, 2008). There is a growing recognition, however, that strong individualist and collectivist values coexist within some societies (e.g., Cheah and Park, 2006; Hastings et al., 2010). This seems to be particularly the case in Westernized Asian cultures such as South Korea, urban China, and India (e.g., Bowker and Raja, 2011; Kim et al., 2008). In these changing societies, parental attitudes, socialization goals, and parenting strategies seem to reflect both traditional Asian values and Western values. For example, whereas Korean culture is rooted in a traditional collectivist ideology, the Korean War and industrialization brought with them an emphasis on the success of one's own family, which encouraged greater competition. These recently adopted Western values are reflected in contemporary Korean mothers' negative view of their children's SW (Cheah and Park, 2006). Moreover, Korean mothers prioritize child-centered goals when trying to promote their social behaviors (e.g., making children feel good about themselves, trying to understand children's perspectives), which also reflects individualist values. Korean mothers, however, attribute their children's SW to external causes, which reflects the traditional collectivist ideology that personalities are largely products of environmental factors rather than innate factors. Thus, in the context of sociocultural shifts, changing cultural norms are reflected in parents' attitudes about children's SW as well as in their parenting goals and strategies (Hastings et al., 2010).

BI and SW in Peer Relationships

Peer relationships are one of the main socializing settings for children, and children's behavior among peers provide a meaningful indicator of their social competence. Withdrawn children are more likely than sociable children to experience neglect and rejection by peers, and to be victimized through chronic bullying by their peers (Rubin et al., 2009). One potential reason for this rejection is that peers view withdrawn children as not complying with age-specific behavioral norms. Another possibility is that withdrawn children lack age-appropriate social skills and are seen as easy targets for victimization (Rubin et al., 2009).

Peer interactions deserve special attention because they are not only affected by the unsociable behavior of withdrawn children but also can influence the developmental trajectory of children's SW. Oh et al. (2008) identified groups of US children with different developmental trajectories for SW across the period from fifth grade to the final year of middle school: *low stable* (children who were not classified as withdrawn at any point in the study), *increasing SW*, and *decreasing SW*. Children who experienced high levels of peer exclusion and victimization were more likely to be categorized as withdrawn in fifth grade. Increased SW over the subsequent years was predicted by friendship instability, the absence of a mutual best friend, or having a best friend who was highly socially withdrawn. Decreased SW was predicted by decreased rejection and peer victimization during the transition to middle school. These findings suggest that having a positive peer context and having friends who model more outgoing behavior may encourage socially withdrawn children to engage in social interaction, effectively reducing their SW.

Norms for peer interaction vary across cultures, and thus how peers respond to BI and SW differs across cultures. For example, shy children in China are viewed less negatively by peers than shy children in the United States and Canada (Chen and French, 2008). In addition, cultural shifts across history

have yielded cross-cohort differences in how adaptive these behaviors are. For example, researchers have found that social adjustment outcomes vary between cohorts of shy elementary school children in urban China (Chen and French, 2008). Shyness was associated with positive outcomes – such as peer acceptance and leadership – in a 1990 cohort, but with negative peer reputation and school maladjustment in a 2002 cohort. Similar to what has been found in other Asian countries, recent social and economic changes in urban China have introduced individualist values such as self-assertion, and this has led people to view inhibited behaviors as suboptimal in the new competitive environment. In rural areas of China, however, where less dramatic economic and cultural changes have taken place, strong traditional collectivist values persist and shy children continue to experience a positive reputation among peers (Chen et al., 2011).

Each of the subtypes of SW may be evaluated differently by peers. Coplan et al. (2007) examined how young Canadian children perceived SW when presented hypothetical vignettes describing the behaviors of shy, unsociable, aggressive, and socially competent children. They found that as early as kindergarten, children distinguished between the different motivations behind SW, and preferred a shy playmate over an unsociable playmate. Similarly, Chen et al. (2011) found differences in the social adjustment of unsociable and shy school-aged children in rural China; unsociability was linked with peer rejection, whereas shyness was associated with peer- and teacher-rated social competence.

Emotional and Cognitive Outcomes of BI and SW

Self-Concept and Coping

Children identified as extremely shy or avoidant tend to experience many social difficulties, such as neglect and peer rejection. Due to frequent negative peer interactions, withdrawn children tend to attribute their social failures to internal factors rather than to their peers or to contextual factors (Wichmann et al., 2004). Consequently, these children are at a greater risk for developing a poor self-concept. Moreover, withdrawn children commonly use avoidant coping strategies – such as doing nothing rather than active problem solving – when they are faced with challenging social situations (Markovic et al., 2013). Researchers suspect that the main obstacles to proactive coping for these children are overarousal in social situations and self-defeating appraisals of their social skills. Such negative appraisals and low self-esteem can contribute to the development of internalizing problems.

Internalizing Problems

Many studies across cultures have found that early BI and SW are associated with internalizing problems, such as anxiety, depression, and loneliness. The relation between SW and anxiety can be considered transactional – one can reinforce the other and therefore the association between the two often persists longitudinally. SW and depression have also been associated in many studies; this might be due to withdrawn children's lower self-esteem, loneliness, or their use of avoidant coping strategies. For example, a longitudinal project in Canada found that childhood SW predicted loneliness and depression in adolescence (Rubin et al., 2009). In a study that followed up Norwegian children from infancy to early adolescence, SW was contemporaneously and longitudinally linked to anxiety and depression (Karevold et al., 2012).

Psychological outcomes vary depending on the subtype of SW and the cultural context. Among the different subgroups of withdrawn school-aged children in Canada, Coplan et al. (2013) found that avoidant children reported the highest levels of social anxiety and depressive symptoms, shy children reported moderately high levels of social anxiety and depressive symptoms, and unsociable children reported levels comparable to nonwithdrawn children. A different pattern was found among school-aged children in rural China, where strong traditional, collectivist values are held: unsociability, but not shyness, was associated with depression (Chen et al., 2011). Thus, whether a specific subtype of SW is adaptive depends on the cultural context.

Interesting associations between SW and psychological adjustment are found in Westernized Asian cultures, where people engage in some individualist behaviors within traditional collectivist contexts. Among Korean college students, shyness during adolescence is only weakly associated with emotional distress, reflective of the collectivist context; unsociability is not related to relational difficulties or to emotional distress in college, which is consistent with the pattern found in individualist cultures (Kim et al., 2008). These findings suggest that as long as children's preference for solitude does not disrupt group harmony, it might not compromise their socioemotional adjustment in such societies. Bowker and Raja (2011) found a similar pattern for unsociability among Indian adolescents, but additionally found that social avoidance was associated with loneliness. Avoidance strongly contrasts with the collectivist value of group cohesion and thus might be especially maladaptive in such cultural contexts.

Finally, evidence suggests that links between SW and psychological adjustment vary by gender in Western societies. Withdrawn boys are at a greater risk for negative outcomes; they are more likely to be excluded by peers and experience socioemotional difficulties across the life span compared to withdrawn girls (Rubin et al., 2009). This gender difference might be partly due to the differences in cultural and parental expectations for boys and girls; BI and SW are seen as less socially acceptable for boys than for girls in Western cultures.

Social Cognition

From an evolutionary standpoint, researchers have recently proposed that a reserved approach to novelty, including social novelty, might have provided the foundation on which humans were capable of making significant social cognitive advances, including advances in their understanding of how others think, their theory-of-mind (ToM). Indeed, human toddlers are more cautious toward novel stimuli compared to humans' closest primate cousins – bonobos, chimpanzees, and orangutans (Hermann et al., 2011) – all of which young children surpass in social cognition. Researchers have started to directly examine relations between SW and the ontogeny of

social cognition, and have demonstrated that some forms of SW are related to more advanced social cognition in children.

Harrist et al. (1997) used teacher ratings of US children's behavior to identify a group of non-withdrawn children, as well as subgroups of withdrawn children, including those who were unsociable, shy (whom Harris et al. term *passive-anxious*), and actively isolated. Social cognition was measured by presenting children hypothetical situations in which they were rejected or ignored when trying to enter a social group or in which another child bothered them. For each situation, children were asked, among other things, to recall the situation and to judge whether the story characters were acting mean (such judgments are called 'hostile attributions'). Kindergarteners who were categorized as *actively isolated* – who were more impulsive, angry, and defiant – had the poorest recall of the situations compared to other withdrawn and non-withdrawn children; and during elementary school, these children made more hostile attributions than the other withdrawn children. In contrast, unsociable children and shy children made fewer hostile attributions during elementary school, even when compared to non-withdrawn children.

Wellman et al. (2011) examined relations between dimensions of US preschoolers' temperament – including shyness, perceptual sensitivity, and aggression – and their ToM. When children were aged 3 years and 5 years, parents completed questionnaires about their children's behavior, and children were given ToM tasks in the laboratory. For the ToM tasks, children were presented scenarios where a character holds a false belief and children were asked to predict and explain characters' beliefs and behavior. Wellman et al. (2011) found that children who were shyer, more perceptually sensitive and less aggressive at the age of 3 had a more advanced ToM at the age of 5. Thus SW may have advantages; shy children, especially those who are nonaggressive and socially attentive, may learn more about others by watching from the periphery of social interaction, compared to their non-shy peers.

Lane et al. (2013) assessed relations between different forms of SW and ToM in two cultures that differed in their social norms concerning shyness: the United States and China. Two types of children were identified using parent ratings of SW and data on children's HPA axis reactivity (gauged via salivary cortisol). Withdrawn children with lower HPA reactivity evidenced more advanced ToM (gauged with false-belief tasks). However, withdrawn children with relatively high HPA reactivity evidenced poorer ToM. Parents' ratings of children's behavior along other dimensions helped to further distinguish the two groups. Withdrawn/high-reactive children had poorer perceptual sensitivity, poorer inhibitory control, and lower levels of smiling and laughter than other children; thus these children would fit the profile of disruptive, socially avoidant children. In contrast, withdrawn/low-reactive children did not differ from non-withdrawn children on these other dimensions; thus these children would fit the profile of shy children.

Lane et al. (2013) found that the social cognitive differences between these two groups were especially marked for Chinese children – withdrawn/low-reactive (i.e., shy) children were especially likely to outperform withdrawn/high-reactive (i.e., disruptive and avoidant) children. As discussed earlier, this likely reflects cultural differences in behavioral norms and expectations. In China, reactive behavior is more discouraged than in the United States, whereas shy or reticent behavior is more encouraged (Chen and French, 2008). Chinese children in this latter withdrawn group might be more welcomed in or near social situations, providing more and better opportunities to learn about others, enhancing their social cognition (Lane et al., 2013).

Suway et al. (2011) assessed how US 2-year-olds' BI and peer interaction jointly predict their ToM at 3 years. BI was measured by observing children's behavior while they were introduced to novel stimuli. Children's peer interactions were measured by pairing each child with an unfamiliar peer; the two engaged in collaborative tasks and the child's negative behaviors (e.g., grabbing, demanding) were recorded. Among children with fewer negative peer interactions, BI at the age of 2 was unrelated to their ToM (essentially, false-belief understanding) at the age of 3. However, among children with more negative peer interactions, BI at the age of 2 predicted poorer ToM at the age of 3. Consistent with the findings of Harrist et al. (1997) and Lane et al. (2013), these latter children appear to fit the profile of disruptive, socially avoidant children who have poorer social cognition.

To summarize, a shy, reticent temperament appears to promote social cognitive development, perhaps because shy children spend more time observing others interact and reflecting upon what they observe. In contrast, withdrawal that reflects greater reactivity and that is characterized by more aggressive, disruptive behavior might undermine social-cognitive development by compromising the quality of the social interactions in which children engage and observe.

Future Directions

Research over the past several decades has focused heavily on social and emotional difficulties associated with BI and SW. Yet, recent studies suggest that there are also benefits associated with SW. For example, BI in infancy predicts better effortful control during the preschool years (e.g., Rothbart et al., 2011), and SW is associated with greater prosocial behavior during the elementary school years (Oh et al., 2008). Recently, research has documented more advanced, or at least precocious, social cognition among shy preschoolers compared to their nonshy peers. Such work should inspire additional research on cognitive, emotional, and social advantages associated with BI and SW. Given the importance of social cognition in our daily interactions with others, it is worthwhile for researchers to examine whether precocious social cognitive abilities translate to greater social competence for these shy children. Research is also needed to examine whether relations between shyness and competencies such as effortful control and social cognition are specific to the preschool years or whether there are more long-term advantages to having a shy temperament.

Studies on cultural variability in the prevalence and developmental outcomes associated with BI and SW have increased over the past decade. Yet, as is the case with much cross-cultural research, these studies are limited to a selected group of countries – namely, those in North America, Western Europe, and East Asia – that have the academic and research infrastructures

to easily support these sorts of investigations. This means that still relatively little is known about BI and SW within, for example, cultures in South America, Africa, and the Middle East. Research with other cultures would serve to further evaluate hypotheses regarding cultural influences on social development. A particularly interesting avenue for research involves tracking the development of BI and SW in countries that are undergoing sociocultural shifts and increasingly incorporating the values and norms of other cultures. Finally, more research is needed to examine the influence of demographic variables (e.g., parents' education, family income) on parents' perceptions of and reactions to children's behavior; this research would likely shed light on intracultural differences in the development of BI and SW.

Abstract

Behavioral Medicine is the interdisciplinary field of study of behavior in health and disease. Based on often-experimental investigations of behavior, behavioral medicine contributes to a better understanding of etiological factors and mechanisms, but also to clinical applications aimed at systematically improving health in clinical and at-risk populations. As the literature summarized in this article illustrates, behavioral medicine has shown tremendous progress in achieving these goals since its inception in 1977. Nevertheless, the successful translation of research results into clinical practice remains a challenge for the future.

Definition and Conceptual Framework

Definition

In 1977, behavioral medicine was defined as "the interdisciplinary field concerned with the development and integration of behavioral and biomedical science knowledge and techniques relevant to health and illness and the application of this knowledge and these techniques to prevention, diagnosis, treatment, and rehabilitation" (Schwartz and Weiss, 1977, 1978). Over the last 30 years, the emergence of several overlapping disciplines may have contributed to a reorientation in the definition of behavioral medicine. The medical specialty of psychiatry adopted the term, often using it as a synonym for its traditional focus on psychopathology. An increase in the promotion and use of therapeutic approaches in complementary and alternative medicine, which is typically based on the interaction of biological, psychological, social, and spiritual influence on health, also involves behavioral approaches and expanded the boundaries of behavioral medicine.

A broader, and more current, definition comes from the charter of the International Society of Behavioral Medicine, which states that behavioral medicine is the "interdisciplinary field concerned with the development and integration of psychosocial, behavioral and biomedical knowledge relevant to health and illness and the application of this knowledge to prevention, etiology, diagnosis, treatment and rehabilitation" (International Society of Behavioral Medicine).

The primary targets of behavioral medicine are physical conditions, although there is increasing recognition of the importance of mental disorders if they are comorbid with physical conditions, whether they are involved in the development of the physical condition or are a consequence thereof (Evans et al., 2005; Prince et al., 2007).

The Biopsychosocial Model

The definition of behavioral medicine implies that it is based on a biopsychosocial model of health and disease. The biopsychosocial model is a general model positing that biological, psychological (which includes thoughts, emotions, and behaviors), and social (e.g., socioeconomical, socio-environmental, and cultural) factors, all play a significant role in health and disease. It follows, that health and disease are best understood in terms of a combination of biological, psychological, and social factors rather than purely in biological terms. This is in contrast to the biomedical model of medicine that suggests every disease process can be solely explained in terms of a deviation from normal function such as a physiological processes, infections, genes, developmental abnormalities, or injuries. In addition to behavioral medicine, the model is used in fields such as medicine, nursing, health psychology and sociology, and particularly in more specialist fields such as psychiatry, family therapy, clinical social work, and clinical psychology.

The model was developed by George L. Engel, a psychiatrist at the University of Rochester, and putatively discussed in an article published in 1977 in Science, where he posited "the need for a new medical model" (Engel, 1977). In an article published a few years later (Engel, 1980) he illustrates this model in detail by applying it to the fate of a hypothetical patient with coronary heart disease. In contrast to a classical biomedical approach, which focuses on the investigation of pathophysiological processes and the intervention at organ-, tissue-, and cell-level, biopsychosocial care would comprise a systematic (behavioral) analysis of typical personality traits and coping behaviors, which may impede admission to hospital in good time or impair medical treatment in any other way. For example, if personal ways of responding to a failed arterial puncture are not taken into consideration (e.g., fainting due to sympathetic hyperarousal), cardiac arrest may be the result. At the social level, the stabilizing role of partners and other forms of social support are also taken into account.

While behavioral medicine aims to include biopsychosocial aspects in research and treatment, there is often such a breadth of information at the individual (clinical) level that it is difficult to derive specific action strategies from it. Indeed, the biopsychosocial model has been criticized extensively for its lack of specificity that renders it untestable, according to some critics. Psychiatrist Niall McLaren summarizes his critique as follows: "Since the collapse of the 19th century models (psychoanalysis, biologism, and behaviorism), psychiatrists have been in search of a model that integrates the psyche and the soma. So keen has been their search that they embraced the so-called 'biopsychosocial model' without ever bothering to check its details. If, at any time over the last three decades, they had done so, they would have found it had none" (McLaren, 2006). In his view the biopsychosocial model should be viewed in its historical context as an alternative to

biological reductionism, which was (and still is) dominating the medical sciences.

The Evolution of Behavioral Medicine

Historical Development

Behavioral medicine emerged in the 1970s as an interdisciplinary field aimed at integrating knowledge from the behavioral and biomedical sciences to improve the understanding of biopsychosocial processes in the development of disorders and the maintenance of health. The term behavioral medicine was used first in the title of a book called 'Biofeedback: Behavioral Medicine' (Birk, 1973). This was predated by earlier experimental results by Neal E. Miller on instrumental learning in paralyzed rats, providing the basis for research investigating the effects of behavioral processes (e.g., learning) on autonomic processes. Although later attempts to replicate his main findings were unsuccessful, these results sparked the inquiry into behavioral, physiological, and biochemical interactions with health and illness, and eventually gained prominence under the rubric of behavioral medicine. In 1976, in recognition of this trend, the National Institutes of Health created the Behavioral Medicine Study Section to encourage and facilitate collaborative research across disciplines.

The 1977 Yale Conference on Behavioral Medicine and a meeting of the National Academy of Sciences were explicitly aimed at defining and delineating the field to guide future research. Based on outcomes of the Yale conference, Schwartz and Weiss proposed the biopsychosocial model, emphasizing the new field's interdisciplinary roots and calling for the integration of knowledge and techniques broadly derived from behavioral and biomedical science. Shortly thereafter, Pomerleau and Brady (1979) published a book, in which they offered an alternative definition focusing more closely on the particular contribution of the experimental analysis of behavior in shaping the field.

Additional developments during this period of growth included the establishment of learned societies (the Society of Behavioral Medicine and the Academy of Behavioral Medicine Research, both in 1978) and of journals (the Journal of Behavioral Medicine in 1977 and the Annals of Behavioral Medicine in 1979). In 1990, at the inaugural International Congress of Behavioral Medicine in Uppsala, Sweden, the International Society of Behavioral Medicine was founded to provide an international focus for professional and academic development, through its currently more than 20 daughter societies and through its own peer-reviewed journal (the International Journal of Behavioral Medicine).

Current State of the Art

Behavioral medicine has firmly established itself over the last three decades as an interdisciplinary field, integrating knowledge from the behavioral and biomedical sciences relevant to health and disease and the application of this knowledge to prevention, assessment, treatment, and rehabilitation. Since its inception in the 1970s it has seen enormous growth and diversification, with new disciplines such as genetics, life course epidemiology, and health economics, and new techniques such as neuroimaging and ambulatory assessments now contributing and adding to the more traditional approaches of behavioral medicine, such as the investigation of the role of personality for disease processes and purely laboratory based approaches. This development was paralleled by the emergence of new, global health concerns such as obesity and metabolic disorders that present new challenges for the integration of the behavioral sciences and public health (Steptoe, 2010).

The more traditional behavioral medicine approaches such as the laboratory based investigation of psychological factors and their effects on psychophysiological responses have been expanded to include the assessment of intracellular processes, cell signaling molecules, and gene expression. Psychophysiology, psychoneuroimmunology, and psychoneuroendocrinology have converged in the shared exploration of behavioral processes across a range of medical conditions. Assessment techniques have been further developed to now include sophisticated measures of ambulatory assessment such as ecological momentary assessment and the day reconstruction method enabling the investigation of behavioral processes in study participants' own environment thus contributing to better ecological validity. Behavioral medicine intervention and prevention research has embraced new information technologies such as the Internet, and new perspectives such as public health, while an increasing number of meta-analyses of intervention trials targeting a range of conditions and patient populations provide the basis for improved care through the integration of single trial results.

Defining the Context

More people than ever die today from preventable chronic diseases of the cardiovascular system, respiratory disorders, or metabolic conditions. Psychological and social factors play an important role in the etiology and the maintenance of these disorders. Mental disorders, which often accompany physical conditions and which have been shown to negatively affect their prognosis, account for the largest part of the global burden of disease. If the risk factors for these disorders were to be reduced through behavior change, life expectancy would rise by approx. 10 years across the globe. The following section gives a brief outline of the context in which behavioral medicine is placed and thus the challenges that it faces.

Morbidity and Mortality in the Twenty-First Century

Epidemiology

Ever since the end of the eighteenth century a significant change in the prevalence of certain disorders and causes of death in the populations of larger countries seems to have taken place. If only 150 years ago the main causes of death were related to infectious diseases, this has changed at the end of the twentieth and the beginning of the twenty-first century to non-communicable, chronic-degenerative disorders. For example, in the European Region of the World Health Organization (i.e., European member states, the former member states of the Soviet Union, Turkey, and Israel) 86% of all deaths and 77% of the total disease burden are attributable to chronic disorders, such as cardiovascular disorders, cancer, mental

problems, diabetes, lung disorders, and musculoskeletal disorders. Among these, cardiovascular disorders rank highest, with more than half of all deaths being accounted for by cardiac disease or stroke.

At least partly responsible for this development is the successful prevention and treatment of infectious diseases, which – together with better hygiene and nutrition – has led to an ever increasing life expectancy. This has resulted in a higher percentage of older people in the population, who are also more likely to suffer from age-associated chronic-degenerative disorders. Nevertheless, there are probably also other reasons, which have contributed to the increasing prevalence of chronic conditions.

Behavioral Risk Factors

Seven leading risk factors have been identified as contributing to almost 60% of the disease burden in the European Region: high blood pressure, tobacco smoking, alcohol, high cholesterol, obesity, a diet low in fruit and vegetables, and physical inactivity. For mortality, high blood pressure is the most important risk factor, while for disease burden it is tobacco smoking. Alcohol is the most important risk factor in terms of mortality and disease burden in younger age groups.

Willett (2002) estimated the percentage rates of four prevalent conditions that could be prevented by long-term behavior modification. According to his estimates more than 80% of type 2 diabetes cases could be avoided, and 80% of coronary heart disease cases; for colon cancer and stroke the corresponding percentage is 70% each. These figures mean that type 2 diabetes, coronary heart disease, colon cancer, and stroke would be avoidable in a substantial number of cases if people did not smoke, engaged in a minimum of 30 min per day of physical activity, were normal-weight, consumed fewer than three alcoholic drinks per day, ate red meat fewer than three times per week, and took folic acid in sufficient amounts.

These figures illustrate in an impressive way the effects of behavior (change) on the etiology and prognosis of physical disorders, including prevention. Ezzati et al. (2003) estimated for which conditions behavior change would have the biggest impact, and concluded that ischemic heart disease, depression, and stroke are ranking first among preventable conditions, particularly in developed countries. If risk factors for these disorders were significantly reduced life expectancy would rise on average by 9.3 years globally.

Consequences for Health Care and Social Systems

Chronic disorders pose a serious challenge for health care systems and consume substantial resources. For example, in Denmark it is estimated that currently 70–80% of health care costs are accounted for by chronic conditions, whereas in the United Kingdom 8 out of 11 hospital-admissions are due chronic disorders.

Nevertheless, the economic consequences of chronic disorders go far beyond the immediate costs for the health care systems. Indirect costs, e.g., losses in productivity due to ill-health are equally as high and sometimes even supersede direct health care costs. In Sweden, for example, over 90% of the total costs for musculoskeletal disorders are indirect costs: 31.5% are accounted for by absenteeism and 59% by early retirement.

Premature death of principal earners and skilled workers not only affects the income of private households but also the national economies of entire states. In 2005, for example, chronic disorders were responsible for a loss of 1% of the gross domestic product across the member states of the Russian Federation; according to these estimates stroke and diabetes produced a loss in income of 11 billion US dollars.

In the middle (e.g., Baltic Sates, Romania, Ukraine, Belarus) and eastern countries of the European Region (e.g., member states of the Russian Federation) people die at a much younger age from chronic disorders compared to Western countries. An additional problem arises due to the aging population in most countries. Currently it is estimated that in 2050 more than a quarter of the global population will be older than 65 years. Age-related multimorbidity is already the rule rather than the exception (Agborsangaya et al., 2012).

Socioeconomic Status and Health

Within countries chronic physical and mental disorders are much more prevalent in lower-income sections of the population. People with lower socioeconomic status (SES) often have twice the risk to fall seriously ill compared to people with higher SES. In addition, high-SES groups benefit more from health behavior change interventions (Marmot et al., 2012).

Psychological Factors and Physical Disorders

Concepts and Disciplines

The notion that psychological factors contribute to the development of physical disorders has a long tradition in history, and in the health sciences in the twentieth century. Based on mostly psychoanalytical concepts psychosomatic approaches stipulated a list of disorders where psychological factors were considered to be particularly important or even crucial for their etiology. This notion, however, has long been abandoned based on empirically supported evidence showing that psychological factors can play an important role for all disorders, contributing either to their etiology, their maintenance, or their prognosis. In disciplines such as health psychology and clinical psychology, or interdisciplinary fields such as behavioral medicine the dichotomy of 'psychogenic' versus 'somatogenic' has been given up in favor of an integrative understanding of psychological and physiological processes in the etiology, treatment, and prevention of chronic physical conditions.

Interactions

(1) Psychological factors can contribute to the etiology of disorders, (2) psychological problems can be the consequence of physical disorders, and (3) they can affect their prognosis.

1. *Causal role in the etiology*. Several possibilities, how psychological factors exert their influence on the etiology of physical disorders exist, and they are not mutually exclusive. First, psychological factors, problems, or disorders can have direct, pathophysiological consequences. For example, depression is associated with neurobiological changes, which increase the risk for the development of chronic pain syndromes (via changes in the serotonergic system; Covic et al., 2006), coronary heart disease (for example through sympathetic overactivity; Brotman et al., 2007), or breast

cancer (e.g., reduced immune function; Oerlemans et al., 2007). Second, psychological factors, problems or disorders as well as adverse socioeconomic circumstances can increase the risk for health-damaging behaviors, e.g., increases in tobacco and alcohol consumption, unhealthy dietary behavior, physical inactivity, and sexual risk taking. Third, the chronic physical condition and the psychological disorder have shared, but independent risk factors ('shared underlying etiology model'). Cerebrovascular changes, for example, are characteristic for depression and Alzheimer's Disease. The underlying process may be a long-term inflammatory mechanism, which is mediated by immune cells. Fourth, the (medical) treatment of a mental disorder may increase the risk for physical conditions through toxic side effects, as is the case, for example, for antidepressants, which contribute to weight gain and have cardiovascular side effects.

2. *Psychological problems are the consequence of the physical disorder*. First, some physical conditions affect the brain directly, as is the case, for example, in some infectious disorders (e.g., HIV), cerebrovascular conditions (e.g., stroke because of high blood pressure or atherosclerosis), basal ganglia disease (e.g., Parkinson's Disease), lung disorders (e.g., neurocognitive abnormalities because of lack of oxygen in chronic obstructive pulmonary disease). Second, receiving the diagnosis of an incurable, chronic condition is a highly stressful event for most patients, in particular if the condition is life threatening or requires significant lifestyle changes. This can increase the risk for mental disorders, for example adjustment disorder in HIV, hypoglycemia anxiety in type 1 diabetes or panic disorder with agoraphobia in chronic obstructive pulmonary disease (Vögele and von Leupoldt, 2008). Third, psychological problems can arise as a consequence of treatment side effects. Certain drug treatments, for example, can contribute to anxiety disorders and depression, as is the case for pain medication (e.g., NRSA), antihypertensive medication, cell division inhibitors (cytostatic drugs), and corticosteroids (cortisone).
3. *Psychological factors affect the prognosis of the physical condition*. Once a physical condition has been established, the future development of this disorder is significantly affected by the patient's beliefs or explanatory model, the patient's self-management of the disorder (e.g., medication adherence), risk behaviors (e.g., tobacco smoking, alcohol consumption, dietary behavior), stress and comorbid mental disorders. There is a large body of literature demonstrating the negative impact of psychological problems or mental disorders on the prognosis of physical conditions. For example, depression doubles mortality risk in patients with coronary heart disease, and this effect is independent of other risk factors such as obesity, tobacco smoking, blood lipids, diabetes, and high blood pressure (Barth et al., 2004).

Methods and Applications in Behavioral Medicine

As an integrative discipline, behavioral medicine involves diverse methodologies and research paradigms that converge on health and disease. Major health problems such as cardiovascular disorders, cancer, lung disorders, obesity, and HIV are, therefore, explored from multiple perspectives. Rather than providing a list of disease-oriented sections, the following gives a brief summary of methods and applications with a focus on clinical practice (for a comprehensive review see Steptoe, 2010).

Assessment

Assessment in behavioral medicine encompasses such diverse approaches as the conceptualization and measurement of health behaviors (e.g., dietary behavior, physical activity, sexual behavior, treatment adherence), self-reported well-being and other psychological processes and outcomes (e.g., mood and negative affect, lay representations of illness and treatment, neurocognitive outcomes), social and interpersonal processes (e.g., social interactions, social support, social networks), socioeconomic and sociodemographic variables, genetic and biological markers (e.g., candidate gene and genome-wide association studies, laboratory stress testing, neuroendocrine measures, noninvasive assessment of autonomic function), and brain function and neuroimaging. Even statistical procedures (e.g., structural equation modeling, mediation analyses) and forms of data reporting (e.g., meta-analyses) have recently been discussed with a focus on behavioral medicine and the specific challenges posed by the wide range of different research paradigms and measures (see Steptoe, 2010).

While assessments in research will depend on the research questions asked, and may in principle cover the entire range of possible methods outlined in the previous paragraph, assessments in clinical practice are often limited due to practical reasons and ethical considerations. The most frequently employed assessment methods in clinical behavioral medicine practice are questionnaire-based self-report measures on mood, well-being, and health behaviors; semistructured and structured interviews for the assessment of mental disorders (e.g., Structured Clinical Interview for DSM Disorders); and routine medical data provided in patient records. Despite increasing recognition among clinicians of the importance of assessing psychological factors in patients with physical conditions, the systematic evaluation and application of disease- and patient-oriented assessment strategies in clinical behavioral medicine practice is still some way off.

The following section gives a brief summary of the most important elements of clinical assessment in behavioral medicine.

Lay Representations of Illness and Treatment

Lay representations of illness and treatment (or subjective explanatory models) are of crucial importance for the course of disease, the patient's way of coping with the disorder, the patient's medical adherence, and their limitations in a range of life areas. Even patients with the same disorder and comparable disease status, can differ in their view of treatability, prognosis, limitations in life, or need for retirement. Important elements of lay representations of illness and treatment are the patient's personal view of the causes of the disorder, which physical symptoms are signs of the disorder, what the course of the disorder will be like, which limitations are associated with the disorder, and possible ways of taking control of the course of

the disorder. An important question concerns the patient's expectation of the degree of his or her own role for improvement or cure. If coping strategies are recognized on the part of the patient, this generally has a positive effect on recovery, independent of their actual efficacy.

For example, lay representations of illness and treatment predict to a significant degree, if and when coronary patients return to work (Petrie et al., 1996). Also for neurological disorders such as multiple sclerosis, patients' explanatory models are the most important predictors of social and psychological impairments, exhaustion, and self-esteem (Jopson and Moss-Morris, 2003). Interventions designed to optimize patients' illness representations have been shown to significantly benefit recovery after myocardial infarction (MI; Petrie et al., 2002).

Cognitive Styles

In addition to subjective explanatory models, other cognitive processes, such as catastrophizing or trivialization of physical symptoms, can impact treatment outcome or prognosis. In a longitudinal study on cardiac patients, for example, 'threat minimization' and 'search for affiliation' assessed only days after a MI both predicted lower depression scores 2 and 6 months after the MI, respectively, suggesting an important prognostic role for cognitive appraisal processes in the early period after a cardiac event (Vögele et al., 2012). The assessment of cognitive styles of coping with the disorder is, therefore, important and should be taken into account when planning interventions (Van Damme et al., 2004).

Coping and Adherence to Treatment

Ways of coping with the experience of (chronic) physical illness range from denial, to collaboration, and constant worrying. These different coping styles evidently affect illness behavior, and, therefore, the course of the illness and quality of life. A particularly sensitive and important area affected by coping styles concerns adherence to treatment, e.g., taking medication reliably, cooperation with invasive medical procedures (chemotherapy, injections etc.), and regular checkups. These areas are, therefore, very important to include in the assessment and monitoring of the patient over the course of treatment.

Avoidance

Avoidance behaviors are a frequent form of illness behavior, which often interfere with treatment goals and, therefore, overall improvement. This is particularly true for chronic pain conditions where avoidance of, e.g., painful movements all-too-often replace the initial source of pain, as, for example, in musculoskeletal disorders involving back pain. It is, therefore, necessary to assess avoidance behavior in the beginning of the therapeutic process, as it is important to motivate the patient to accept a possible, but transient deterioration in physical symptoms in the short-term, in favor of a mid- and long-term improvement.

Resources

Even patients with chronic physical conditions that involve serious limitations (e.g., amyotrophic lateral sclerosis, cancer at an advanced stage) can experience good quality of life, dependent on a number of environmental factors (e.g., good social support, adequate care) and psychological strengths (e.g., self-regulation strategies). Following Antonovsky's approach of salutogenesis (Antonovsky, 1987) and also current conceptualizations of health (Jadad and O'Grady, 2008) such resources are crucial for patients' well-being and quality of life, and should, therefore, be part of any clinical assessment with the aim to integrate these resources into individual behavioral medicine treatment formulations.

Interventions

Treatment of Comorbid Mental Disorders

Distress, demoralization, and comorbid mental disorders such as anxiety and depression negatively affect the prognosis of physical conditions, either via direct, physiological consequences or indirectly, through behaviors such as treatment adherence or health-risk behaviors, or both. If depressed, cardiac patients, for example, have a significantly worse prognosis than nondepressed cardiac patients (Barth et al., 2004). Nevertheless, mental disorders not only deserve adequate treatment because of their negative impact on the physical condition; mental disorders must be addressed in their own right, given their negative impact on patients' quality of life.

1. *Clinical-psychological interventions*. The clinical psychological treatment of mental disorders comorbid with physical conditions principally encompasses all interventions, which are empirically supported with regards to their efficacy and are, therefore, currently used in the treatment of those with mental disorders. Cognitive behavioral techniques are demonstrably among the most successful intervention methods in the treatment of depression and anxiety disorders, i.e., the most frequent comorbid mental conditions. Nevertheless, cognitive behavior therapy approaches need to be frequently adapted to the specific conditions that are determined by the physical disorder. For example, physical symptoms usually considered being typical symptoms for a panic attack (e.g., light headedness, shortness of breath, racing heart, sweating) can also be a consequence of the physical disease, i.e., not only as a result of catastrophizing cognitions. In the cognitive reframing of physical symptoms, patients are, therefore, required to learn to differentiate between symptoms that occur unrelated to external causes (i.e., panic attack) from those that are associated with an acute deterioration of their physical condition (e.g., stronger shortness of breath because of an infection, trembling and sweating because of hypoglycemia). An important role concerns the identification of unrealistic, catastrophizing cognitions (e.g., "Now I am going to die," "Because of my shortness of breath, I am going to instantly suffocate"). The aim of modified cognitive behavior therapy in the treatment of comorbid mental disorders in patients with chronic physical conditions is to enable the patient to better assess how realistic such cognitions are, in particular in relation to the severity of the disorder (e.g., blood glucose awareness training for diabetic patients with hypoglycemia anxiety; Cox et al., 2006), and/or to emotionally disengage from them (mindfulness-approaches in the treatment of anxiety disorders and depression in chronic obstructive pulmonary disease; Fjorback et al., 2011).

2. *Drug treatment*. Comorbid mental disorders in patients with physical conditions are also treated using psychopharmacological interventions, however with mixed success. The more successful drugs include Serotonin Reuptake Inhibitors, in particular in the treatment of depression in Parkinson's Disease, coronary heart disease, HIV, and rheumatoid arthritis. Nevertheless, drug treatments necessitate the consideration of specific side effects (e.g., cardiovascular side effects, weight gain, etc.). In addition, after terminating drug treatment, symptoms often reoccur. In some cases, for example in the treatment of depression in diabetes, drug treatment and clinical-psychological interventions are combined with the aim to initially improve mood and increase drive and motivation through medication to enable the patient to fully benefit from cognitive behavior therapy. The antidepressive medication can then be reduced in a systematic fashion to prevent relapse.

Health Promotion and Support in Disease Management

1. *Stress management programs*. Stress management programs positively affect immune parameters, neuroendocrine responses, and further recovery outcomes. They are, for example, successfully employed in the treatment of people with HIV (Antoni, 2003) and cancer (Phillips et al., 2008). Their success, however, is related to the professional quality of their implementation. Stress management programs are usually conducted in a group format and combine any of the following elements: relaxation trainings (e.g., progressive muscle relaxation), cognitive reframing (changing dysfunctional cognitive styles, adjustment of realistic treatment goals), education (effects of stress on immune function, drug effects, and side effects), and communication training (anger management, assertiveness training). The aim of these programs is the improvement of self-efficacy and perceived control, and the acquisition of functional coping strategies as well as the training of strategies to improve social support.
2. *Patient education programs*. Patient education programs are conceptually closely linked with stress management programs. They were inspired initially by patient education programs for diabetics (Shelley et al., 2004), and then adapted for other chronic physical conditions, for example cardiovascular disorders (Dusseldorp et al., 1999). Central to these programs is not only information and education, but also the empowerment of patients. Techniques used to achieve these therapeutic goals include principles of motivational interviewing, as they have been used in health promotion programs for other chronic conditions such as drug and alcohol dependence.
3. *Relaxation trainings*. While relaxation techniques include a range of practices, e.g., progressive muscle relaxation, guided imagery, self-hypnosis, and deep breathing exercises, they all have the aim of inducing a state of relaxation characterized by slow breathing, lower blood pressure and heart rate, and a feeling of calm and well-being. As is the case for stress management programs, the success of relaxation trainings depends to a large extent on the quality of their implementation. Factors that have been shown to affect the efficacy of relaxation trainings include the structuredness of their implementation, the professional competency of the trainer, and flexibility in adapting the training to the specific requirements of the patient. They are successfully implemented in the psychological treatment of chronic pain, the reduction of side effects of invasive medical procedures, and in the treatment of neuropsychological deficits (for a meta-analytical review see Carlson and Hoyle, 1993).
4. *Biofeedback*. Biofeedback aims at gaining greater awareness of and, thereby, learning to influence physiological functions that are usually not under voluntary control (e.g., heart rate, blood pressure, brain waves, muscle tension). This is achieved by monitoring these physiological processes with psychophysiological equipment and feeding the activity back to the participant using graphic displays on a computer screen or auditory information (e.g., tones). Recent meta-analyses demonstrate the success of biofeedback in the noninvasive treatment of a range of chronic physical conditions, such as migraine, tension headache, chronic back pain, hypertension, incontinence, epilepsy, and tinnitus (for an overview see Schwartz and Andrasik, 2003). The Cochrane Library alone currently lists 41 entries on meta-analyses with the term biofeedback appearing in their title, abstract, or keywords. Nevertheless, like for many behavioral medicine interventions, the future challenge is to further systematize biofeedback implementation and to develop guidelines for its use in clinical practice for reasons of quality assurance.
5. *Interventions to reduce instrumentally reinforced problem behavior*. The aim of this behavior therapy approach is to reduce problem behavior (e.g., avoidance behavior in chronic pain or after stroke) by interrupting the reinforcement chain, which leads to avoidance of everyday activities and problem behavior. Positive and negative reinforcers are identified in a functional assessment to change these contingencies using contingency management techniques. Frequently the collaboration of carers, family, or friends is required as they often, inadvertently reinforce the patient's problem behavior. Particularly successful areas for this approach include the treatment of chronic pain, some neurological conditions (Parkinson's Disease, stroke, acquired brain injury; Alderman and Wood, 2013) and substance misuse.

Conclusion

Behavioral medicine is the interdisciplinary field concerned with the integration of knowledge from the behavioral and biomedical sciences relevant to health and disease, and the application of this knowledge to prevention, assessment, treatment, and rehabilitation. Since behavioral medicine's inception more than 30 years ago, enormous progress has been made in the understanding of biopsychosocial interactions. The inclusion of new techniques has expanded to the assessment of intracellular processes, cell signaling molecules, and gene expression. Assessment techniques now include sophisticated measures of ambulatory assessment such as ecological momentary assessment and the day reconstruction method enabling the investigation of behavioral processes in study participants' own environment thus contributing to better

ecological validity. Behavioral medicine intervention and prevention research has embraced new information technologies such as the Internet, and new perspectives such as public health, while an increasing number of meta-analyses of intervention trials targeting a range of conditions and patient populations provide the basis for improved care through the integration of single trial results. This development, however, was paralleled by the emergence of new health challenges such as HIV, obesity, metabolic disorders, and chronic obstructive pulmonary disease, and a growing recognition of the importance of mental problems and mental disorders comorbid with physical conditions. In contrast to this progress in scientific knowledge, the translation of study results into clinical practice is lacking. It remains a challenge for the future to develop treatment and assessment guidelines and to systematically evaluate their effectiveness thereby contributing to the continuing optimization of patient care.

Behavioral Problems, Effects of Parenting and Family Structure on

Abstract

Parental behavior aims to provide care and socialize the child according to cultural norms and expectations, and has an independent effect on the child's behavior. Research has provided evidence that parental hostility/rejection, lack of warmth/support, and failure to provide adequate control is associated with behavioral problems such as aggression, defiance, and antisocial behavior. However, the underlying causal mechanisms are still in doubt. Contemporary models of the development of behavioral problems emphasize reciprocal parent–child interactions; family structure has an indirect effect on behavioral problems through parenting, family relationships, and socioeconomic factors. Evidence from behavioral genetics and remaining questions are presented.

Behavioral problems (destructiveness, aggression, defiance, rule breaking, stealing, and vandalism) are also described as externalizing problems. Disruptive behavior is the most common form of child and adolescent maladjustment; moreover, early and persistent behavioral problems are associated with multiple adverse outcomes in later life, including compromised mental and physical health, impaired educational attainment, unemployment, poor social relationships, substance abuse, and criminality, and create a substantial burden to society in terms of suffering and financial cost.

Although different sorts of behavioral problems are interrelated, there is accumulating evidence for distinct subtypes (Tremblay, 2010). It is useful to distinguish between overt (physical aggression, temper tantrums, opposition, and defiance) and covert (rule breaking, stealing and vandalism) behavioral problems. Physical aggression includes behaviors directed toward another individual with the intent to cause physical damage, e.g., hitting, kicking, pushing, beating, etc. Overt nondestructive behaviors include the following: losing temper, disobeying adults, openly refusing to comply with rules, annoying and blaming others. Covert behavioral problems include antisocial acts such as truanting from school, running away from home, use of alcohol and drugs, stealing, burglary, and destruction of property.

Development of Behavioral Problems

It is important to recognize developmentally normative level of behavioral problems and to distinguish it from an abnormal behavior. Longitudinal community studies have shown that overt behavioral problems tend to increase until the second or third year of life and peak between 2 and 4 years (Tremblay, 2010). Thus angry, aggressive, oppositional, noncompliant, and impulsive behaviors are common in toddlerhood and so are often considered developmentally normative, although this period is described as 'the terrible twos.' After the preschool years, overt behavioral problems decrease steadily to the end of adolescence and throughout adulthood, as children learn to use socially acceptable behavior, some considerably better than others.

Covert behavioral problems appear later than overt problems; they are very rare before middle childhood and increase with age until about 17 years. Thus antisocial behaviors (rule breaking, running away, substance abuse, vandalism, and theft) are very common in adolescents, suggesting that adolescence-limited delinquency is normative rather than abnormal. Most adolescents desist from antisocial behavior in young adulthood – possibly because they have learned that it leads to punishment, – and become increasingly motivated in fulfilling adult role expectations (Moffitt, 1993).

There are substantial differences in frequency and seriousness of behavioral problems and these differences appear remarkably stable from early childhood onward. Longitudinal studies show that children who display aggressive, oppositional, noncompliant, and impulsive behaviors most frequently in toddlerhood, will continue to do it most frequently throughout childhood. Furthermore, the small group of children (around 7%) who continue to show high levels of behavioral problems during middle childhood, are those most at risk of aggression, violence, and antisocial behavior during adolescence, and later in life too. For these children, behavioral problems remain stable (lifetime persistent) and lead to more serious maladaptive outcomes (Moffitt, 1993). Therefore, psychiatric classifications in the late 1970s recognized 'Conduct Disorder' as a medical condition, and nowadays it is one of the commonest psychiatric disorders in children and adolescents.

It is important to explain why and how some young children develop persistent behavioral problems whereas others develop normally. There is good evidence that early development of behavioral problems has its origin in the child's continuous interactions with the immediate environment, particularly with their primary caregivers.

The Diversity of Family Structures

Family is a domestic group of close people and the principal institution for childrearing. There is tremendous diversity of family structures both within and between cultures and over time (Georgas et al., 2006; Roopnarine and Gielen, 2005). In recent decades most countries have seen significant structural changes in families as a result of sociodemographic changes and globalization, and these changes are similar across traditional, developing, and developed countries. Worldwide, birth rates have been declining steadily, reducing the number

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23047-X

of children in the family. This is accompanied by a decrease in marriage rates and increases in rates of single parenthood, divorce, separation, remarriage, and cohabitation.

Family structure around the world has been gradually changing from the traditional extended and multigenerational families that include parents, children, and other relatives, to more nuclear families comprising parents and children. However, the conventional nuclear family consisting of two married parents (the working father and the housekeeper mother) and their children has become less common in the developed world. More children are born to unmarried parents or a single mother and they may experience changes in family structure throughout childhood and adolescence. These processes, along with a higher proportion of working mothers and elderly people, lead to a wide variety of family arrangements in which nuclear families, including single-parent, cohabiting, reconstituted, nonresidential-father, and same-sex families, are embedded in a network of extended kin that serve the purpose of childrearing (Georgas et al., 2006).

Although rates of specific family structures differ markedly across cultures and ethnicities, marriage still has a key role in family formation, and women are the primary child caregivers worldwide (Georgas et al., 2006; Roopnarine and Gielen, 2005). Recent surveys (e.g., Chapple, 2009) reported the highest rates of two-parent families in Asian, Middle Eastern, and Southern European countries that are strongly influenced by traditional and religious values (more than 80% in China, India, Turkey, Spain, and Greece) and the lowest rates in America, Australia, and Northern Europe (less than 60% in the United States and around two-thirds in Denmark and Iceland). Rates also vary by ethnicity, e.g., in the United States in 2010, approximately 75% of non-Hispanic white children and 35% of black children aged below 17 years, lived with two parents.

Overall, in developed countries, about three-quarters of the children live with both parents, about 15% with a single parent, about 9% in a stepfamily, and 2% in other arrangements. Although point estimates suggest that most children live in two-parent families, life course estimates indicate that more than half of all children will spend some time in another form of the family (two-fifths in a cohabiting family). In the Nordic countries the rates of cohabiting families are particularly high (45% of all births in Sweden), and this is accompanied by institutionalization.

Lone-parent families are increasing around the world and 80–90% of them are headed by women. In the developed countries, the rise is mainly due to increases in divorce, separation, and the number of single mothers who never married or cohabited; in the developing countries paternal labor migration, imprisonment, or death are more important. However, for many children raised in lone-parent families, nonresident fathers or other father figures may play a prominent role. Although labor migration may alienate fathers from their children (Roopnarine and Gielen, 2005), limited evidence suggests increases in paternal involvement over recent decades.

The Concept of Parenting

Parenting refers to childrearing behavior, as well as related beliefs, knowledge, values, and attitudes (Bornstein, 2002). The primary parenting goals involve providing appropriate care and socializing the child according to cultural norms and expectations. Parental attitudes may emerge long before the child's birth, but after birth, parenting develops in reciprocal interaction between child and caregiver in the wider sociocultural context.

Therefore, parenting varies markedly with the child's age, gender, and other physical and behavioral characteristics, and also across different caregivers, and from culture to culture. Parental personality plays an important role and behavioral genetic studies suggest a genetic influence. Parental mental health, family relationships, socioeconomic status, social network, and other factors are also important. Parental attitudes, values, and beliefs are likely to influence parental behavior, which, in turn, has an independent effect on the children. However, parental attitudes may differ significantly from actual behaviors; for example, parents who are under stress may treat their children in ways that they consider undesirable or inappropriate. In extreme cases, adverse parenting may take the form of child maltreatment, such as abuse and neglect.

Decades of research and clinical studies have led to multidimensional and multilevel concepts of parenting. Several typologies of parenting have been suggested and a large number of specific dimensions have been identified. However, at present there is no widely accepted theory of parenting (O'Connor, 2002) and no well-validated system for classifying parental behaviors. For research and applied purposes, parenting has been assessed by direct observations, interviews, or questionnaires. Observations are made in the playroom or in the home, are expensive and time consuming, and may not be appropriate with older children and also for some behaviors (e.g., corporal punishment). Standardized questionnaires or rating scales completed by parents and older children can be useful in community surveys. Despite a large number of measures developed over recent decades (Locke and Prinz, 2002), there is still a need for assessment techniques that might be relevant to the origin and development of behavioral problems and can be used with families from diverse backgrounds.

Dimensions of Parenting

Two main dimensions of warmth and control have consistently emerged in many studies across childhood and adolescence and across cultures and methods of measurement. The warmth dimension reflects the affective component of parenting, characterized by sensitivity, responsiveness, involvement, and support. There is some evidence that it is better to consider warmth/support and hostility/rejection as separate dimensions, since they are conceptually different and uniquely related to the child's behavior.

The control dimension reflects parental efforts to influence the child's behavior, such as enforcing rules, applying discipline, and supervision. Different types of parental control have very different implications for child development. Schaefer in the 1960s and later Steinberg distinguished between psychological control and behavioral control. Psychological control aims to influence the child's feelings and thoughts by verbal disapproval, love withdrawal, conditional regard, and guilt induction. Behavioral control, in contrast, aims to influence the

child's behavior by setting limits, enforcing rules, and monitoring maturity demands.

Parental disciplinary practices have received considerable attention both in research and practice. Positive discipline involves induction, i.e., reasoning, explanation and reminding of rules, and reinforcement of desired behavior through praise and rewards. Punishment is used to reduce undesired behavior through unpleasant consequences, such as expression of disappointment, verbal criticism, shaming, the raised voice, withdrawal of privileges, 'time out,' or physical punishment. Physical punishment ranges from the mild occasional light smack, to controlled conditional or customary spanking, to severe corporal punishment (e.g., hitting or beating), to physical abuse.

Some other dimensions of parenting have been widely used in research and practice. Coercive control refers to parental efforts to influence the child by use of force, physical manipulation, or commands. Harsh parenting involves coercive control, corporal punishment, and verbal aggression (e.g., yelling or scolding). The structural dimension concerns parental efforts to create a predictable and organized environment for the child, enforce house routines and a stable set of rules, supervision, and consistency in discipline.

Beside the dimensional approach, much research on parenting has used categorical classifications proposed by Baumrind in late 1960s and then modified by Maccoby and Martin in 1983. Based on the levels of two main dimensions of warmth and control, four parenting styles have been identified: authoritative (high warmth, high control), authoritarian (low warmth, high control), indulgent/permissive (high warmth, low control), and neglectful/uninvolved (low warmth, low control). It was supposed that parenting style conveyed the parents' general attitude toward the child and the emotional atmosphere in which parenting behavior occurred. However, because of doubts about the validity of parenting typologies, the focus of recent research moves toward specific parenting behaviors and cognitions and reciprocal interaction patterns between child and caregiver (Bornstein, 2002). Beyond the traditional parenting research exploring the role of mothers, an increasing number of studies consider fathers and other caregivers.

Associations between Parenting and Behavioral Problems

Research has provided abundant evidence that behavior problems in children and adolescents are related to the parenting they receive in their families. Studies have particularly emphasized the role of ineffective or negative parenting, such as hostility/rejection, lack of warmth/support, and failure to provide adequate control. By contrast, responsiveness, involvement, support, and positive control, such as approval, inductive reasoning, appropriate limit setting, firm and consistent discipline, and monitoring is associated with fewer behavioral problems.

Lack of supervision, and harsh and inconsistent discipline have all been linked to aggression, delinquency, and other disruptive behaviors. Neglect and extremely harsh, abusive parenting practices significantly increase the risk of aggression, criminality, and violence. There is continuing controversy over the effects of physical or corporal punishment. Historically, it has been widely used and accepted as a disciplinary method; one meta-analysis provided evidence for negative long-term consequences. However, compared with other disciplinary practices, controlled conditional spanking was most effective for reducing child noncompliance or antisocial behavior; physical punishment led to worse outcomes only when it was too severe or was the primary disciplinary method. Harsh verbal discipline such as yelling or scolding is uniquely related to child problem behavior, as well as psychological control. The link between inconsistent discipline and behavioral problems appears to be direct and independent of child's effects. Although parental monitoring has been linked to less delinquency, recent evidence indicates that this association reflects parental knowledge due to adolescent free disclosure and not to active parenting behavior.

Numerous studies have shown that an authoritative parenting style is associated with less behavioral problems, while authoritarian, permissive, and neglectful parenting styles can all contribute to the child's disruptiveness, aggression, delinquency, and antisocial behavior. There is some evidence that a psychologically controlling parenting style is associated with delinquency and with relational social and indirect aggression. Overall, the main findings on parenting and behavioral problems have been confirmed across contexts, ages, and cultures, although the cultural context may have an important role (Bornstein, 2002).

Theoretical Framework

Several theoretical models have been proposed to account for the association between parenting and behavioral problems. For much of the twentieth century, psychoanalytic and learning theories have been particularly influential. Psychoanalytic theories emphasized the importance of caregiving experiences received in early childhood, but provided inadequate explanatory models of development. Early learning theories have been formulated in the behaviorist tradition suggesting that all behaviors are learned and that parents increase desired behavior through rewards and reduce undesired behavior through punishments.

Social learning theory, developed by Bandura in the 1960s, suggests that the child can learn behavior through imitation by observing other people and emphasizes the importance of parents as role models. According to social learning theory, children acquire disruptive behavior such as aggression through direct modeling when parents use harsh verbal discipline, corporal punishment, and abusive practices. Learning theories considered the child as a passive recipient of parenting influences, but Bell in 1968 pointed out that children had effects on their parents, just as parents had effects on their children. Understanding of reciprocal parent–child interactions then led to the elaboration of transactional models (Dodge and Pettit, 2003).

The Coercion model, developed by Patterson in the 1980s, suggests that children's disruptive behaviors tend to elicit verbal aggression and physical punishment and if parents do not encourage appropriate behavior and do not consistently apply discipline, children's disruptive behavior may escalate because this enables them to get more attention, avoid

unpleasant demands, or get their own way. Thus parents may unintentionally reinforce tantrums, noncompliance, aggression, and antisocial behaviors, which in turn lead to less parental involvement, warmth and consistency, and harsher discipline. An escalating cycle of coercive parent–child interactions is supposed to be the main cause of high trajectories of behavioral problems from early childhood to adulthood, and the empirical evidence has supported this causal mechanism.

There are other possible mechanisms through which parenting is linked to child behavioral problems. Internalization of social norms is enhanced by positive parenting, which fosters attachment, provides inductive reasoning, and promotes autonomy and intrinsic motivation for good behavior; and it is compromised by harsh parenting which prevents the formation of secure attachment, provides strong pressure for compliance, fosters an external locus of control, and precludes the development of internal attributions. Cognitive processing of social information may also be important, so that children who have experienced hostile and harsh parenting are more likely to selectively attend to hostile cues, attribute hostile intent to others, access aggressive responses, and believe that violence and antisocial behavior is beneficial. Parenting may also influence self-regulatory capacities, such as effortful control and emotional regulation and the underlying physiology.

Contemporary models of the development of behavioral problems suggest that a specific combination of early temperament and parenting may lead to hostile coercive exchanges from toddlerhood onward. Dadds and Salmon (2003) emphasize interaction between parental disciplinary practices and the child's sensitivity to punishment. A dynamic cascade model designed by Dodge with colleagues, suggests that biologically based difficulties in impulse control and behavioral regulation initiate the chain of development of antisocial behavior from early childhood through adolescence, in which parents, family, and the wider environment play the crucial roles.

Effects of the Direction of Parenting-Behavioral Problem

Though the links between parenting and behavioral problems in children are well established, the effects are typically mild or moderate and the underlying causal mechanisms are still in doubt. Several research approaches have been suggested for studying the effects of parenting (O'Connor, 2002). Prospective studies showed that parenting predicts subsequent behavioral problems in children and adolescents, even when the initial level of the problem is taken into account. Overall, warm and responsive parenting has been linked with decreasing behavioral problems, whereas harsh parenting predicted smaller decrease in physical aggression in schoolchildren and increasing delinquency in adolescents.

More recent studies have demonstrated that change in parenting over time is associated with subsequent change in behavioral problems. For example, decrease in parental support, increase in rejection, and inconsistent discipline predicted increase in the child's behavioral problems. Sequential analyses of parent–child interactions have shown that parental use of coercive control and corporal punishment increases the likelihood of disruptive behavior in the child. These findings provide stronger support for the effect of parenting on behavioral problems but the evidence is indirect.

Experimental interventions designed to enhance parental effectiveness and to improve behavioral problems have the possibility of proving causal effects. Parenting interventions promote mutually rewarding activities, and teach parents to reward good behavior, to provide clear instructions, and consistently apply discipline by a firm and calm response such as 'time out.' Numerous randomized controlled trials have shown the effectiveness of parent training for childhood conduct disorders. Limited evidence from community-based studies suggests that altering parental behavior can lead to changes in the child's behavioral problems. For example, in one study of recently divorced mothers and their school-age sons, intervention produced benefits to coercive discipline and positive parenting, which in turn prevented noncompliance from growing over 2.5 years, in contrast to a control group. Although change in parenting behavior leads to improved child behavior, this does not necessarily mean that poor parenting is the cause of behavioral problems, just as symptomatic medication alleviates physical illness but it does not cause the disease itself.

The Role of Genetic Factors

Over recent decades, behavioral genetic studies provided evidence of an important role for genetic factors in both parenting and children's behavioral problems. At the same time, twin and adoption studies have shown that the effects of shared family environment are often weak or absent. These findings have led to the conclusion that parenting has little effect on child development. Although most studies showed a greater contribution from shared environment to disruptive behavior in the child, it has been argued that the associations between parenting and behavioral problems were almost entirely due to the genetic transmission. Developmental research addressed these misconceptions (Collins et al., 2000) and designed approaches that examine the causal relations and the processes involved (Moffitt, 2005).

Meta-analyses suggest that genetic factors account for about for 40–50% of individual differences in antisocial behavior and the contribution of shared environment is about 15–20%; the rest of the variance is accounted for by environmental influences that are not shared by children in the same family and by measurement error. The smaller effect of shared family environment as compared to nonshared, does not mean that family influences are unimportant; it only means that they tend to make siblings more different than similar to each other. The influence of shared family environment may be even larger because estimates of genetic influence include not only the direct effect of genes, but also the indirect effects of environmental factors. There is limited evidence that genetic effects may vary depending on the type of behavioral problems and age: genetic contribution to physical aggression in children from 1.5 through 6 years was higher (around 60%) and more stable than genetic contribution to disregard for rules (around 30%). Individual differences in parenting behaviors are also influenced by genes, with estimates ranging from 25 to 60%.

Genetic factors may have a role in linking parenting to children's behavior problems. Genetic transmission can explain up to half of the association between bad parenting and child aggression (Moffitt, 2005). Genetic child effects are also important. For example, children's genes accounted for most of the correlations between corporal punishment and children's aggression and between negative parenting and adolescent antisocial behavior, indicating that children's behavioral difficulties may evoke negative parenting and corporal punishment, but the reverse does not apply.

Nonshared environmental influences that make children growing up in the same family different have received much research attention. While early behavioral genetic studies estimated environmental effects as a residual, more recent studies used direct measures of family environment. For example, the 'Nonshared Environment in Adolescent Development' project used multiple measures of parenting and adolescent antisocial behavior longitudinally in identical and fraternal twins, full siblings, half-siblings, and genetically unrelated siblings. Studies using the full multivariate genetic design found significant, albeit small, nonshared environmental effects of parenting, such as parent–child mutuality and conflict, parental negativity, criticism, corporal punishment, and physical abuse, on children's behavioral problems, independent of genes and shared environment. A recent review concludes that important sources of nonshared environment may be epigenetics and children's differential experiences. Recent twin and adoption studies suggest that stability of children's behavioral problems is mainly accounted for by genetic (60%) and shared environmental influences (34%); the effect of nonshared environment is much smaller (6%).

Interactive Effect of Genes and Parenting on Behavioral Problems

Although developmental researchers have long been aware that genes and environment constantly interact, it was difficult to detect statistically significant interactions. Recent findings suggest that parents of children at genetic risk for disruptive behavior can effectively reduce the level of behavioral problems if they provide warmth, support, and positive control, and suppress negative and harsh parenting. For example, one study showed that parental monitoring and supervision protected adolescents from the genetic risk for conduct disorder.

Animal studies suggest that early parenting can influence gene expression and lead to a stable and lasting change in genetic effects. In addition, early parenting may affect biological programming of brain development, cognitive and emotional processing, stress responses, and social interactions. These mechanisms suggest that parenting effects may be transmitted intergenerationally; therefore, preventive interventions for serious behavioral problems should begin earlier than is current practice – before a child is born (Tremblay, 2010) – and target high-risk parents and the larger family.

Interactions between Parenting and the Child's Temperament/Personality

In the 1950s Thomas and Chess proposed that goodness-of-fit between parenting and children's individual characteristics plays a key role in the emergence of behavioral problems. Although this idea lacked empirical validation for many years, recent studies provide clear evidence that similar parenting may have different effects on children with different temperaments/personalities. Many studies have focused on difficult temperament characterized by irritability, low adaptability, and negative mood. The evidence suggests that the combination of a child's difficult temperament and poor parenting carries a particularly high risk for behavioral problems, while temperament, parenting, and family structure in themselves may have little effect. However, the findings were not entirely consistent – possibly because the concept of difficult temperament was not well defined.

Other studies focused on specific dimensions of parenting and specific temperament/personality traits and found a number of interactive effects on behavioral problems. In many instances, interactions corresponded to a dual-risk pattern whereby certain traits amplified the negative effects of parenting. For example, harsh and hostile mothering was a stronger predictor of behavioral problems in irritable children than in placid ones. Many studies have shown that children with low effortful control, high impulsivity, low conscientiousness, and low agreeableness are more affected by parenting than children with better self-control. By contrast, high effortful control protected children from the negative effects of maternal hostility, inconsistent discipline, and physical punishment. Thus certain temperaments/personalities can protect children against the negative effects of poor parenting.

Belsky's differential susceptibility hypothesis suggests that children may differ in the degree to which rearing environment may affect their development. Pluess and Belsky (2010) concluded that children who seem most susceptible to poor parenting may also benefit the most from developmentally supportive rearing across infancy, toddlerhood, and later childhood. For example, children high in negative emotionality were most vulnerable to the effects of unsupportive, rejecting, or intrusive parenting, but also benefited most from intervention programs.

Other interaction patterns were described by O'Connor and Dvorak in 2001. There is limited evidence that some children develop problems only if they receive ineffective parenting, whereas other children have high levels of conduct problems irrespective of the kind of parenting they received. One such trait is child psychopathy that includes low fear, callousness, and constricted emotionality. More generally, specific parenting dimensions and child temperament/personality traits operated differently, depending on the particular combination. In one study, physical punishment predicted increases in behavioral problems in boys high in anxiousness and low in frustration, but had the opposite effect in boys low in anxiousness and high in frustration.

Family Structure and Children's Behavioral Problems

Contextual models of child development particularly emphasize family effects on behavioral problems. Because an increasing proportion of children around the world live with the lone mother, the father's presence in the home has received considerable attention. Recent meta-analyses indicate that

children growing up in two-parent families tend to do better across a range of domains than children raised by a lone parent and the effects continue from the childhood and teenage years into adulthood (Chapple, 2009). The largest effect, as estimated by standardized mean difference, was found for behavioral problems (around 0.30).

Although these differences are well documented, the direction of effects is still unclear. A lone parent family may have a causal role in initiating and maintaining child behavioral problems, the influence may be reverse, and both lone parenthood and child behavioral problems may reflect the operation of a third factor, whether psychosocial or genetic. Several research designs are useful for estimating causal effects, however the evidence is not conclusive yet. One study found that children benefited from a father's presence only if he exhibited low levels of antisocial behavior; when fathers were antisocial, the longer they lived with their children, the more behavioral problems their children had. Overall, the effect of the father's presence on child behavioral problems depends on the father's support, involvement, parenting practice, and also on family relationships and socioeconomic factors.

Divorce may be followed by aggressive and antisocial behavior, but this is more due to prior and continuing marital discord than to separation from one of the parents. Generally, consequences of divorce tend to wane within a few years, the remaining negative effects result from a decrease in available resources and the quality of parenting, especially supervision. There is some evidence that each family transition carries additional risk, so that children are far more likely to have behavioral problems when they experience two or more parental divorces and/or remarriages. Although nationwide surveys consistently show that children in stepfamilies and single-parent families have on average higher probabilities of behavioral problems than children growing up with two married biological parents, the effect is small and varies markedly. The risk is mostly accounted for by socioeconomic factors, psychological stress, and family relationships, not by family structure per se.

Gender Differences

After the age of 4, behavioral problems are more common in males than females; the differences are most pronounced for physical aggression. Studies do not show marked gender differences in early childhood, therefore, different socialization of boys and girls is thought to play a key role. Socialization models emphasize that from birth, parents differentially encourage and punish boys' and girls' behaviors. Although there is no strong evidence for gender differences in parenting during infancy, in childhood boys tend to receive less warmth, less monitoring, harsher discipline, and more corporal punishment than girls. However, these differences may be accounted for by child effects. Overall, associations between parenting and behavioral problems do not differ between boys and girls; however, recent research suggests that interactive effects of temperament such as effortful control, may have a role.

There are clear differences between mothers' and fathers' parenting in many cultures. Mothers are more involved in caregiving in the early years of life, while fathers' involvement with children has been more limited until fairly recently. Research evidence suggests that children's behavioral problems are more closely associated with maternal than with paternal parenting; however, the underlying causal mechanisms are far from certain. Evidence is accumulating that both the child's and the parent's gender may be important. Studies show greater parental involvement with same-gender children, and recent meta-analysis found that paternal parenting was more likely to differ by child gender than maternal parenting. Researchers have hypothesized that parenting and behavioral problems are more closely associated in same- than in opposite-gender parent–child dyads, because children tend to imitate a same-gender model more, but the evidence is contradictory. Meta-analyses do not support the suggestion that boys from single-mother families are more likely than girls to have behavioral problems because of the absence of male role model, but they do show that in the 1990s, divorce had stronger effects on boys than girls.

Age Differences

Both parenting and the child's behavior changes with age; thus there may be developmental changes in the effects of parenting and family structure on behavioral problems. Studies show that consistent with a cumulative reciprocal model of parent–child influence, the association between parenting and behavioral problems is larger in older children than in toddlers and preschoolers; however, the link between corporal punishment and aggression is most pronounced in school-age children and monitoring becomes increasingly important in adolescence.

Parental age may also be important. Adolescent mothers tend to be more physically intrusive and punitive, and their children have been shown to be at higher risk of adverse outcomes, although recent evidence suggests that these effects are due to the third factors rather than early childbearing. The role of grandparents is controversial. Although they may provide help and support for teenage mothers, several western studies have shown that the multigenerational family structure may have negative effect on adolescent mothers' parenting; findings for children's behavioral problems are inconclusive.

Behavioral Problems in Siblings and Differential Parenting

Many studies have shown that siblings may influence a child's behavioral problems such as aggression, delinquency, and conduct disorder, independent of other risk factors. Within-family differences between siblings are also important. While earlier parenting research included only one child per family, newer approaches tend to focus on sibling differences. One study found that about two-thirds of the total variance in parenting is within families. Differential parenting refers to differences in parental treatment of siblings or to differences in siblings' perceptions of the parenting they receive. Research has shown that parents do treat their children differently, for example, in the 'Nonshared Environment in Adolescent Development' study, between-sibling correlation of parenting was 0.70 for parent reports, 0.25 for child reports, and 0.20 for observations.

Differential parenting is partly explained by sibling differences in gender, age, temperament, and disruptive behavior.

Family structure is also important, with differential parenting being much more common in stepfamilies than other family forms, for both mothers and fathers. One study showed that for mothers, biological relatedness is strongly associated with differential parenting, independent of the child's gender, age, or aggressive/disruptive behavior. Recent evidence suggests that differential parental treatment is related to child and adolescent behavioral problems beyond the absolute level of parenting.

The association between differential parenting and behavioral problems may vary depending on gender, birth order, and sibling relationship. Thus, one study found that in the association between differential parental warmth and adolescent delinquency 1 year later (but only for younger children in same-sex dyads), disfavored boys were reported to have higher rates of vandalism and violence, and disfavored girls were reported to have higher rates of theft; poor sibling relationships enhanced these effects. The role of differential parenting has been explained in terms of the social comparison model and the distributive justice framework, suggesting that siblings actively shape their experiences. Genetically informative studies showed that differential parenting primarily reflects genetically influenced differences between siblings; and differential effects of parenting on behavioral problems are due to genotype–environment correlation. This implies that both family and child effects have a role to play in the development of behavioral problems.

Conclusion

Current research on parenting, family structure and behavioral problems is increasingly benefiting from advances in genetics, neurobiology, psychology, and social science. Contemporary conceptual models emphasize bidirectional processes in parent–child interactions, the role of the family and wider sociocultural context and developmental trajectories. Newer research designs and multivariate analyses of longitudinal data are useful for testing causal influences. However, there is a lack of comprehensive measurement framework for examining the development of parenting and behavioral problems from early childhood through adolescence. There is also a need for comprehensive classification of family structures that applies to diverse backgrounds. It may be valuable to include positive parenting and to examine protective family influences in future research. Finally, a growing understanding of the effects of parenting and family structure on behavioral problems will benefit from cross-cultural research.

Behavioral Problems, Effects of Socio-Economic Status on

Abstract

The association between socioeconomic status (SES) and behavior problems in children is long established and well accepted. Across levels of SES, behavioral problems are generally more common among lower-SES children. However, less is understood about both the mechanisms that underlie these differences and their developmental origins. This article reviews the research regarding material and psychosocial paths that account for socioeconomic differences in child behavioral problems and how these differences are reinforced by social contextual influences within the family, school, and community. The article ends with a discussion about implications of SES differences for clinical care and policy interventions.

What Is Socioeconomic Status?

Socioeconomic status (SES) is a concept that summarizes an individual's social class position in society. Several conceptualizations of SES have been used, including material measures of income, occupation, and education as well as gradient-focused measures of relative status, relative deprivation, or class differences (American Psychological Association, Task Force on Socioeconomic Status, 2007). Although absolute levels of affluence (e.g., household income) are among the most commonly used measures of SES in research, over the past decade there has been increasing emphasis on the ability of social class gradients and perceived SES to better predict various social and behavioral health outcomes (Adler and Snibbe, 2003).

SES in children is typically measured using data on family income, parental occupation, parental education, or a combination of these factors. Although no standard measurement method exists, some methods are more commonly used than others. For example, the Hollingshead Index (Hollingshead, 1975), which was devised initially in the 1940s, is a four-factor index that comprises occupation, education, sex, and marital status. Although widely criticized, the occupational and education scales remain in widespread use. The classification of occupations may be made less useful by the proliferation of job titles that bear little resemblance to job status or income. Annual family income is often used in research; however, this factor may shift dramatically from year to year depending on employment status, overtime hours worked as well as changes in government income transfers and tax credits.

Similar challenges exist in gradient measures of SES. Although assessments of subjective SES share a robust relation to child behavioral symptoms, they also vary over time and context, are influenced by emotional styles, personality traits, or sense of personal control, and depend on how the individual evaluates social position (e.g., based on education, income, housing, or meeting one's potential). Researchers have now begun to explore the hypothesis that relative deprivation, measured in terms of individual income (or a proxy for it) relative to one's reference group, may relate more closely to child behavioral symptoms than absolute difference in income (Elgar et al., 2013). Despite the sensitivity of relative deprivation to both SES and the distribution of affluence in the reference group, currently no consensus exists about the appropriate formulation of relative deprivation and reference group characteristics (Reagan et al., 2007).

Childhood Behavioral Problems

Behavioral problems in children are usually categorized into internalizing and externalizing problems. Externalizing behavioral problems manifest outwardly as aggression, impulsivity, coercion, and noncompliance. Internalizing behavior problems are described as inward occurrences, displaying as an inhibited style described as withdrawn, lonely, depressed, and anxious. Comorbidity occurs both within and across these problems. Accordingly, children with aggression may also be suffering from anxiety or depression. In addition, externalizing and internalizing problems underlie various health and social problems that are more likely to initiate clinical intervention (e.g., physical fighting, body dysmorphism, self-harm).

Why Is SES Important in Relation to Childhood Behavioral Problems?

SES positively relates to behavioral health in every age-group and social context in which it has been studied. The relation is monotonic – meaning that at every level of SES, health and well-being are usually better at the level above and poorer at the level below. Youths from higher SES backgrounds exhibit fewer internalizing and externalizing problems, fewer social skills deficits, and higher life satisfaction (Tremblay, 1999). Because the gradient is found in countries with and without universal access to health services and the effect of SES does not plateau, even among middle- and upper-class families, SES differences in behavioral problems are mostly a psychosocial phenomenon and not attributable to absolute deprivation or poverty (Wilkinson and Marmot, 2003).

The association between SES and behavioral problems in children has received some attention in the epidemiological literature using cross-sectional, cohort, and longitudinal

studies. A recent systematic review by Reiss (2013) examined studies published in English or German between 1990 and 2011 that included at least one measure of SES and identified mental health problems in children and youth using validated measures. Reiss (2013) found that 52 of the 55 studies included in her sample showed an inverse relation between SES and mental health problems. Furthermore, children from families with lower SES were about two to three times more likely to have mental health problems than children from more advantaged families. Although there was some variability, low SES was more strongly associated with externalizing behavior disorders, such as opposition defiant disorder or attention-deficit hyperactivity disorder, than with internalizing disorders such as anxiety and depression. Additionally, SES related more closely to problems in early childhood than in adolescence. Gender differences were not clearly evident. Based on these findings, Reiss (2013) highlighted the need for early childhood interventions to reduce mental health problems in families with low SES.

Singh and Ghandour (2012) found that the odds of exhibiting a serious behavior disorder in children increased 1.9 times if the child lived in an unsafe neighborhood with poor housing, garbage in the streets, and high rates of vandalism; 1.9 times if the parents had less than high school education; and 3.7 times if the child lived in poverty (**Figure 1**). The authors concluded that improvements in neighborhood conditions and household income could reduce child behavioral problems.

The relation between SES and child behavior problems was also illustrated by Vine et al. (2012), who examined SES and anxiety in a cohort study of 498 U.S. middle school children in the age-group of 11–13 years. Annual household income and neighborhood median income were used to measure SES. Anxiety was measured using the four anxiety subscale scores from the Multidimensional Anxiety Scale for Children (MASC) (i.e., physical symptoms, harm avoidance, social anxiety, and separation/panic anxiety). The results were complex and showed that household income negatively related to scores on two of the four MASC subscales – physical symptoms and separation/panic anxiety. In contrast, adolescents living in higher-income neighborhoods with the same level of household income displayed higher physical and harm avoidance symptom scores. This study highlights the need for multiple measures of SES, as simple studies correlating just one measure of SES with global measures of problems can miss potentially important relationships.

Why Are Behavior Problems in Children Important?

According to the National Research Council and Institute of Medicine (O'Connell et al., 2009), about 17% of children and youth suffer from diagnosable mental health problems, with internalizing and externalizing behavior problems being the most common at a prevalence rate of 13 and 11%, respectively.

Behavior problems in children may impact adolescence and adulthood. Although some children recover, many develop chronic and debilitating mental health problems in adulthood, encounter academic problems in school, have difficulty finding long-term employment, and become involved in criminal activity (e.g., Sourander et al., 2005, 2008).

What Are the Mechanisms by Which SES Influences Behavioral Problems?

There are many potential mechanisms by which SES might influence the occurrence of behavioral problems. The influence is complex and challenging to untangle. Developmental research has traced the origins of SES differences in behavioral problems to prenatal exposures to maternal stress; early childhood experiences; and developmental processes that shape neuroendocrine responses to stress and neuroregulatory systems in the brain that govern emotion, attention, and social interactions (Repetti et al., 2002).

Epigenetics, or changes in gene expression due to environmental influences, has been investigated to explain the

Figure 1 Social gradient in behavioral problems (blue line) and prevalence of a serious behavioral disorder (red line) in 91 642 American children. Adapted from data published by Singh, G.K., Ghandour, R.M., 2012. Impact of neighborhood social conditions and household socioeconomic status on behavioral problems among US children. Maternal and Child Health Journal 16 (1), S158–S169.

persistent genomic embedding of early-life experiences, most commonly, socioeconomic stress (Borghol et al., 2012). Mechanisms such as increased cortisol output and inflammatory responses are being proposed and tested (Lam et al., 2012). However, serious methodological challenges in this area abound, and all results must therefore be regarded as preliminary (Heijmans and Mill, 2012).

Research into the causal mechanisms that underlie SES differences in behavioral problems focuses on the direct consequences of material deprivation and the indirect psychosocial consequences of relative socioeconomic position (Adler and Snibbe, 2003). The material path involves an unequal distribution of material resources that can be used to support health (e.g., access to mental health services). In contrast, the psychosocial path involves the notion that *feeling poor* in comparison with others elicits class anxiety and psychological stress, erodes social supports, and thus contributes to increased mental distress (Wilkinson and Marmot, 2001). Although these mechanisms are interrelated, only the psychosocial path explains why children at the same level of household income or parental education might differ in their mental health when one is surrounded by more affluent people and the other by less affluent people (Vine et al., 2012). What differentiate these children are feelings of deprivation from a desirable standard of living that is established by society (Sweet, 2011).

Thus, SES relates to child behavioral problems in part through upward social comparisons of social class. Epidemiological studies of income inequality have found that societies with larger SES differences between the rich and poor (and therefore more relative deprivation) have higher prevalence rates of mental illness and lower well-being in children and adolescents, as indicated by rates of teenage pregnancy (Pickett et al., 2005), school bullying (Elgar et al., 2009), alcohol misuse (Elgar et al., 2005), and school dropout (Pickett and Wilkinson, 2007).

In addition, a third variable might influence both SES and behavioral problems. Genetics, for example, might influence both parental and child behavior and link SES to behavior problems. For example, in a study of 1069 11-year-old twins and their biological mothers and fathers, Bornovalova et al. (2010) demonstrated that parental genetic factors accounted for a large percentage of the variance in disorders in these children.

Some variables may produce intergenerational effects (Yoshikawa et al., 2012). For example, low levels of education and adolescent parenthood are associated with low SES, and these may perpetuate poverty, resulting in effects on behavior problems generations later.

Several other contextual variables exist that may serve to mediate SES with their effect on behavior problems, including abuse; neglect; exposure to violence; poor nutrition; exposure to toxins such as lead; poor neighborhood environment; inadequate and cramped housing; less cognitive stimulation; chaotic home environment; poorer access to good schools; harsh or inconsistent parenting style; parental stress, including depression, anxiety, and isolation; and poor access to effective interventions. All of these variables are more common exposures among lower-SES children.

Although SES is an individual or family attribute, the environments in which low-SES families live differ from those environments inhabited by advantaged families. Poor neighborhoods are more likely to be violent, congested, littered and with inadequate housing stock that is more likely to have toxins, more crowded, and in poor repair. Poor neighborhoods have fewer social resources, poorer schools, and fewer safe play and green spaces. These factors impact on the rate of behavior problems (Singh and Ghandour, 2012) and may also exert an indirect effect via parental behavior (e.g., harsh parenting, low monitoring) or other mechanisms.

What Are the Implications for Research, Clinical Activities, and Policy?

Recent, more sophisticated studies have found that the relation between SES and behavior problems is nuanced and may depend on several individual and contextual factors, including the measure of SES used, subtype of behavior problem examined, child's age, and ethnic or national factors. Thus, in the future, studies may need to take into account the child's context and the specific type of behavior problem. Interdisciplinary collaboration and increasing levels of methodological expertise in this research are critical components. Standardization of measures via guidelines and consensus across the research community might prove effective.

It is also important to consider policy approaches for reducing relative poverty. The corrosive social impacts of economic inequality suggest that children in areas of larger SES differences – not just from low-SES families or deprived neighborhoods – are more vulnerable and a legitimate focus of community and school-based interventions. However, it is critical to realize that behavior problems occur at all levels of society. These problems are not restricted to the poor. In fact, the majority of children with behavior problems are not poor. Consequently, efforts to reduce behavior problems should not be restricted to families of lower SES.

Different strategies have been employed to insure such efforts. Family-focused programs, such as Head Start in the U.S. (Garces et al., 2002), Sure Start in Great Britain (Melhuish et al., 2008), and Educa a Tu Hijo (Educate Your Child) in Cuba (Hertzman et al., 2010), have all improved behavioral and academic outcomes in disadvantaged youths through improving the quality of postnatal health, early childcare, and parenting. Other programs target parental discipline and monitoring, and parent–child communication to treat disruptive behavioral problems and improve health and social development of disadvantaged youths (Dishion et al., 2008; Webster-Stratton and Taylor, 2001). Universal school-based programs have been shown to effectively reduce behavior problems in children (Durlak et al., 2011). Additionally, interventions targeted at changing neighborhood conditions (e.g., garbage, safety) have shown similar positive results (Yoshikawa, 1994).

Standard mental health interventions present considerable access barriers to families who have low SES. These barriers include needing to take time off work to attend sessions, costs of child care, and travel expenses, including parking and meals. In addition, there is often stigma in attending a mental health clinic. Distance treatment systems such as Strongest Families™ (McGrath et al., 2011) that do not require travel schedules and

schedule appointments at times convenient for parents can help overcome these barriers. Olds' program of nurse home visiting (Kitzman et al., 2010) has also been shown to result in long-lasting outcome improvements in a variety of domains, including behavior problems.

Reducing SES differences with respect to child behavior problems is a policy priority in many countries. In 2008, the World Health Organization's Commission on the Social Determinants of Health called for urgent and coherent government action to 'close the gap' in health between the rich and the poor, with a particular focus on early childhood development and education (Irwin et al., 2007; WHO, 2008). This commitment was reinforced in 2011, when the WHO adopted resolution WHA62.14 (Rio Political Declaration on Social Determinants of Health), which compels member states to monitor the social determinants of child mental health. Indeed, social programs that reduce poverty, such as income support for poor families, economic development, and improvements to living arrangements, may decrease behavior problems in children (Yoshikawa, 1994). However, programs that strive to reduce SES differences in child behavior disorders must align with broader social and economic policy in order to change the social conditions that give rise to these differences in the first place.

Abstract

Behavioral theories of organization are a major portion of the field of organizational studies, as behavioral reasoning is found across a range of theoretical approaches. We review the role of behavioral theory in the major research traditions of organization theory, starting with the original behavioral theory of the firm and continuing to evolutionary theory, population ecology, institutional theory, and transaction cost theory. We also address the organizational problems investigated by each theory, and we summarize by noting a trend toward greater integration of the field around behavioral reasoning.

Introduction

Behavioral theories of organization are typically traced back to Cyert and March, "A Behavioral Theory of the Firm," which sought to "develop an empirically relevant, process-oriented, general theory of decision making by a business firm" (Cyert and March, 1963: 3). The 'Behavioral' article was not part of their guidelines for constructing theory; but in order for a theory to be oriented toward the process of making decisions and to be empirically relevant, it had to focus on actual decision-making behavior. Hence, Cyert and March proposed a behavioral theory of the firm (BTOF) as a counterpoint to theories that were not grounded in observation of decision-making processes and were not proven to be empirically relevant for firm-level decisions, although they might still yield useful macro-level predictions.

Modern reviews and reformulations have been divided between attempts to reaffirm this definition of 'behavioral' and attempts to extend it. A recent review reflects this divide, as it is open about the definition in keeping with the general growth and diversification of the behavioral literature, but it also notes that behavioral theories have a common foundation in ideas of individual bounded rationality and organizational procedures for decision making (Gavetti et al., 2012).

Within the field of management, the idea that theories should be built on observation of decision-making processes is currently so conventional that its opposite can seem to have mostly historical value. However, the classical definition of 'behavioral' still has some bite left. Theories of intraorganizational decision making based on equilibrium ideas are not process theories and hence fail the process part of the definition, meaning that agency or contract theory, for example, is not behavioral. If a theory conforms to empirical observation, it may fit the other part of the definition, empirical relevance. Some theories that are phrased at a very high level of analysis also lack a clear process theory of decision making, or they would be consistent with multiple process theories of decision making, and such theories are not behavioral either. Population ecology did not start out as a behavioral theory, although we will argue in this article that it has become behavioral.

The process-oriented view of decision making in organizations necessarily implies a focus on multiple persons, and potentially multiple organizational units, being engaged in decision making. The earliest formulation of the BTOF emphasized this through its theory of problemistic search, which started locally to a problem but expanded if the search did not have a local solution, along with its theory of coalitions in decision making (Cyert and March, 1963). This focus on multiple persons anchors behavioral theories to the meso level of analysis. Although specific treatments can cross levels of analysis and hence look at how the meso level interacts with micro-level or macro-level outcomes, the meso level is unavoidable. Through its emphasis on observable processes, behavioral theory is also heavily focused on organizational mechanisms that produce decisions, rather than decisions as a result of incentives or pressures.

Behavioral theories of organizations need to take into account that behavior is carried out in an organization. Although scholars debate the exact definition of an organization, most definitions agree that organizations are collections of individuals and groups who perform interdependent activities that are oriented toward the accomplishment of goals. Other key characteristics of organizations are that they exhibit some permanence over time and are embedded in an external environment, but theorists differ in whether they see these characteristics as defining or as simply frequent. The defining characteristics have implications for what should be included in a behavioral theory of organization in order to be a complete theory. We think that organizational theory could address at least the problems that are listed in **Table 1**. Indeed, we find that a selection of major theories in the current literature does address these problems to differing degrees. We indicate this with stars designating the theoretical perspective that focuses on their solution. Multiple stars are used to designate that the theoretical perspective emphasizes the particular issue, while a single star indicates that it provides some treatment.

Going down the rows:

1. New organizations and forms spread when organizations of certain kinds become seen as legitimate or efficient means of fulfilling specific purposes. Population ecology predicts when new organizations will appear as a function of the density and concentration of existing firms (Carroll and Hannan, 2000). Transactions cost theory predicts when transactions will occur in the market or in organizations, and hence when new organizations are likely (Williamson, 1991).

Table 1 Theoretical perspectives and organizational problems

2. Forming goals and establishing tasks	*				
3. Dividing and coordinating tasks	*	*			**
4. Motivating members	*				
5. Learning and adaptation	**	**	*	*	*

2. Behavior is motivated toward the achievement of goals. The goals can be divided into subgoals (Cyert and March, 1963), which can be further broken into tasks for individuals to perform. Cyert and March (1963) addressed the development of goals through the concept of aspirations, which are a function of the organization's past performance and the performance of similar organizations. The goals are also affected by the organization's purpose, which is established at its founding and renegotiated periodically. The tasks that individuals perform in organizations are interdependent: accomplishing one task affects the accomplishment of another.
3. These interdependent tasks must be coordinated, which can be achieved through routines, a concept that grew out of the standard operating procedures of the BTOF (Cyert and March, 1963) and was developed fully in the evolutionary theory of the firm (Nelson and Winter, 1982).
4. A behavioral theory of organizations should take into account that organizations are composed of individuals whose participation and performance require motivation.
5. Organizations learn from their experience. This learning is embedded in routines so that knowledge acquired from past experience can affect future performance (Levitt and March, 1988; Nelson and Winter, 1982). Sometimes, the learning is adaptive and results in the organization fitting its environment better; at other times, the learning is maladaptive, and the organization's fit with the environment is not improved. Population ecology also examines the extent to which the organization fits its environment, including adaptive processes that can lead to organizational failure.

Thus, current theories of organizations focus on different organizational problems. Population ecology focuses on the interplay between the organization and its environment and studies how the founding and the death of organizations are affected by the ecology of other organizations and the nature of the environment. Population ecology theories treat organizations as unitary actors, and the early statements of the theory did not examine processes within organizations or permit learning. By contrast, the BTOF explicates the internal processes of organizations by including issues such as coordination, motivation, and goal formation. The BTOF also permits learning. Evolutionary theory also includes issues of coordination and learning from experience, which contributes to path dependence in organizations. Transaction cost theory focuses on which alternatives will be internalized within an organization and which will be achieved through market transactions. However, as we will argue in this article, these traditional boundaries between the theories are increasingly becoming blurred as each theory is addressing new questions. This is a development that seems to be moving the field toward a new integration as a connected (but not single) behavioral theory of the firm, where there had earlier been several separate theories and research traditions with limited communication between each.

Review

Behavioral Theory of the Firm

The BTOF is a research tradition that traces its origins directly to "A Behavioral Theory of the Firm" (Cyert and March, 1963), and its emphasis on organizational learning is closely related to organizational learning theory (Levitt and March, 1988). There is a recent review of the BTOF (Gavetti et al., 2012), so we review this research briefly and with an emphasis on key contributions and recent work.

One branch of this research has taken the statements on managerial decision making as a key feature of this theory. A key feature of the stylized decision maker in the BTOF is a focus on goal variables and adaptation of aspiration levels, and verification of this assumption is a feature of both older and current work. Adjustment of risk-taking propensity as a result of performance relative to aspiration levels was not part of the original formulation of the theory, but it has since become central in work on individual decision making (March and Shapira, 1992), in part as a result of cross-fertilization of ideas with psychology such as prospect theory.

The focus on goals in the BTOF also carries over to research on top management team and organizational levels of analysis. Because behaviors differ as a result of which goals are examined and which parts of the environment are salient, the question of organizational attention comes to the fore (Ocasio, 1997). The effects of attention on organizational action are explored in research on outcomes such as the attention on top management teams and public statements of the organization. This work is closely related to research that integrates the influences of managerial information seeking, managerial characteristics, and responses to performance on decision making.

The BTOF predicts that organizations respond to performance below the aspiration level by engaging in problemistic search. This has been developed into a research stream on performance feedback, which examines how organizational changes result from performance that is below aspiration levels, which in turn adapts as a result of social and historical comparisons (Greve, 2003). Much of this work is at the organizational level of analysis, and it shows effects on

decisions that seem tailored to quickly recover from poor performance such as market entry, investment, and innovation launches (Greve, 2003). These same decisions are risky, however, so the research also shows an increase in risk taking when performance is below aspiration levels.

An important insight in the BTOF is that organizations learn from their experience. The knowledge or intelligence they acquire is embedded in standard operating procedures or routines, which affect future performance. Thus, rather than every action an organization takes being a result of calculation, many actions are a result of enacting routines.

Organizational routines are interdependent task sequences performed by multiple members. Early conceptions of routines emphasized that they conserve lessons from the past and thereby improve efficiency in the future. Routines were conceived as a source of stability in organizations and as representing political truces of how tasks should be performed in organizations. Recent work on routines has emphasized that they are a source of change as well as stability (Feldman and Pentland, 2003) and has conceived the gradual development of organizational routines as an engine of evolution in organizations (Nelson and Winter, 1982).

Two strands of research on organizational learning have taken different stances on the role of organizational experience. One strand, exemplified by research on organizational learning curves, finds that although there is considerable variation in the rate of improvement, experience generally improves dimensions of organizational performance (Argote, 2013). Another strand emphasizes the challenges of appropriately sampling and learning from experience in organizations (Denrell and March, 2001). These two strands of research have become intertwined to some extent, with researchers explaining the variation in the rate at which organizations learn from experience and identifying conditions under which experience is harmful or helpful for organizational performance.

Levitt and March (1988) theorized that organizations not only learn from their own direct experience but also learn from the experience of other organizations. This latter form of learning has been referred to as vicarious learning or knowledge transfer. Considerable research has been conducted over the last couple of decades on the mechanisms through which and the conditions under which one organization learns from the experience of others. Knowledge transfer across organizations plays a key role in evolutionary theories as well as learning theories.

The BTOF has, since the start, shown a concern for the consequences of the behavioral rules that empirical research uncovered. This has led to a rich modeling tradition that shows how different behavioral rules affect organizational performance and adaptation in stable or changing environments (March et al., 2000). Classic findings include work showing the danger of rapid learning of routines or precise reactions to noisy feedback, both of which can cause an inherently inferior strategy to be chosen. This argument was further developed into the famous tradeoff between exploration of new strategies and exploitation of current ones (March, 1991), an argument that has since been shown to be stable across modeling frameworks (Denrell and March, 2001). Difficulties in finding the best strategy or structure comprise an enduring topic in this modeling tradition, and many treatments focus on how the structure of the environment presents traps or how the organizational structure affects decision making and learning (Fang et al., 2010).

Evolutionary Theory

Evolutionary theory is a branch of research that traces its origins back to "An Evolutionary Theory of Economic Change" (Nelson and Winter, 1982), a treatment that shared with Cyert and March (1963) a rejection of maximization assumptions and full rationality. It differed in emphasis by examining the gradual development of organizational routines as the engine of evolution, reasoning through a parallel with human skill development, and thus lacked the emphasis on stability and discrete change events found in the theory of problemistic search (Cyert and March, 1963).

Like learning theory, evolutionary theory has since developed many branches, and a brief review cannot do full justice to this work. A common feature of the work is that it emphasizes path dependence. Evolutionary processes only differ meaningfully from systems with equilibrium features when they are not teleological – they do not evolve toward fixed points that are determined by some maximization process. Rather, multiple end states are possible, and which one is reached depends on early steps that in turn can be the result of chance events or the agency of actors who do not fully foresee the consequences of their actions. Technological paths that get 'locked in' by early events are classical examples of evolutionary processes.

One branch of evolutionary theory examines the evolution of firms. It views the firm as taking on a trajectory determined by its current stock of knowledge and its rules for altering this stock, and it is thus closely related to learning models, although it sometimes blends intraorganizational learning mechanisms with external selection mechanisms (Levinthal and Posen, 2007). The behavioral assumptions are that managers have some ability to choose (short-term) superior options, but are prone to make incorrect judgments when short- and long-term payoffs must be traded against each other. Finally, firm-level evolutionary work often treats issues of how to design the firm as an effective adaptive system. It typically assumes that organizations vary in their designs, but their managers do not fully understand the adaptive consequences of this variation.

Empirically, the research focuses on the transformation and replication of knowledge. Direct investigation of knowledge transformation is challenging, but there has been theoretical and empirical work on how organizations can influence the knowledge acquisition process and thus shape the evolution of routines (Zollo and Winter, 2002). Likewise, there is work showing that organizations can 'fix' routines that have reached a high level of performance in order to prevent experimentation that might lead to lower performance levels and that replicating routines exactly can be associated with higher performance than attempts to adapt routines to local conditions (Knott, 2001). Finally, because evolutionary processes are influenced by the level of variation available to select from, manipulating the proportion of organizational units that are allowed to vary influences the overall rate of change. This can be done through the form of governance or through managerial routines with some local autonomy.

Replication is particularly important because knowledge replication is required in order for an evolutionary theory of the firm to contain something approaching a genetic code (Winter and Szulanski, 2001). Research has shown that firms are indeed able to make routines replicable across units, either with or without planned variation according to local conditions, but in so doing they face the dilemma that replicable routines are also more easily observed and copied by competitors. Researchers have suggested that this dilemma can be resolved by embedding knowledge in transactive memory systems (Argote and Ren, 2012).

Transactive memory systems are collective systems for encoding, storing, and distributing information. Colloquially known as 'knowledge of who knows what,' transactive memory systems capture knowledge of who knows what and who is best at what. Transactive memory systems develop as organizational members gain experience working together, and they are idiosyncratic to organizations because they depend on the particular individuals who are members of an organization. Transactive memory systems are hard for competitors to imitate. Thus, embedding knowledge in transactive memory systems is more effective at preventing knowledge spillover to other organizations than embedding knowledge in routines.

Another branch of evolutionary theory examines the evolution of industries. Research on technological paths has examined how technological choices are shaped by economic factors that favor making the same technological choices as other firms in the same industry, which means that initial leads in adoptions become magnified. Transitions between generations of technologies have also spurred interest among evolutionary theorists, with a particular focus on whether the new technology has characteristics that favor incumbent firms or newly founded firms (Tushman and Anderson, 1986). These empirical studies are built on evolutionary reasoning in which a central assumption is some form of behavioral myopia in which firms pursue immediate incentives, even if these lead them to commit to a technology that will lose in the long run.

Research on the structure of transactions in industries has examined the reconfiguration of transaction interfaces between firms over time. This work has shown how new transaction structures are gradually formed from old ones rather than created anew. This process is seen when industries form additional transactional links, as in the creation of a less integrated industrial structure. It is also observed more generally during periods of industrial formation or change of boundaries between actors, such as those that occur when major new technologies create opportunities (Jacobides and Winter, 2005) or market actors seek to rearrange exchange relations.

Population Ecology

Population ecology theory focuses on explaining organizational foundings and deaths as a function of characteristics of the organization and other organizations in their environment. Population ecologists theorized that selection was the mechanism through which organizations changed (Hannan and Freeman, 1977); organizations that fit their environments were selected and prospered, and those that did not fit their environments perished. Organizational change was seen as rare and likely to harm rather than help an organization's survival prospects (Carroll and Hannan, 2000).

Population ecology has produced a large body of empirical research. Carroll and Hannan (2000) reviewed the population ecology literature and identified important empirical regularities in it. First, studies generally find a liability of smallness: as organizational size increases, failure rates decrease. Second, although a liability of newness was once theorized, recent empirical work that controls for organizational size has found that mortality rates increase with organizational age. Third, the relationship between births and deaths of firms, on the one hand, and the number of competing firms in the environment, on the other, is nonmonotonic. At low levels of firm density, founding rates increase, and mortality rates decrease with increases in density. At high levels of density, however, founding rates decrease and mortality rates increase. The former effect has been attributed to legitimation, while the latter has been attributed to competition.

Although the original statement of population ecology theory argued that selection and not learning or adaptation was the mechanism through which organizations change, more recent treatments have acknowledged that learning occurs, although it is regarded as rare (Carroll and Hannan, 2000). Learning and selection have been productively integrated in models of organizational performance and survival. Another connection between population ecology and learning can be found in studies on the success of new entrepreneurial ventures. Research has found that entrepreneurial firms that spin out of other firms or whose members have previous experience in other firms perform better than those lacking previous experience.

Population ecology theory intersects with institutional theory on the concepts of legitimacy and organizational form. As noted in this article, there is evidence that as the density of a population increases, survival prospects of organizations first increase and then decrease. Population ecologists attribute the initial increase in survival to the increasing legitimacy of the organizational form. An organizational form is perceived as legitimate when it is taken for granted as the appropriate way to accomplish certain collective tasks. An active, current stream of research focuses on organizational form as a specific kind of social identity (Hsu and Hannan, 2005).

Institutional Theory

Institutional theory is a research tradition that traces its origins back to foundational articles that discussed how organizational founding and change were driven less by functional considerations and more by symbolic actions and external influences than the theory at the time assumed (Meyer and Rowan, 1977). These articles drew on concepts of bounded rationality that are central to behavioral theories and sketched a broad range of potential research questions, but much subsequent research drew away from the firm focus on behavioral theories of organization by emphasizing environmental influences such as the diffusion of new institutionalized practices among firms.

As institutional theory has grown, some branches have moved closer to behavioral theory. Direct dialogue between the perspectives has been started by researchers who have noted that the organizational change processes examined by

behavioral theory are influenced by the institutional context (Wezel and Saka-Helmhout, 2006). A growing subfield of institutional theory concerns institutional logics, which are broadly (but not universally) shared assumptions and action patterns (Thornton, 1995). At the organization level, institutional logics can be seen as sources of managerial decision-making rules, and hence institutional logics research is related to research on the BTOF and evolutionary theory.

Institutional theory has also moved into examining the founding conditions for new firms (Tolbert et al., 2011). This work questions the conventional assumption that entrepreneurs are rationally able to locate opportunities, and it instead posits that key sources of organization founding activities are institutional features of the social group to which entrepreneurs belong or the symbolic environment they face. Like population ecology, this work moves the concerns for decision-making processes and bounded rationality to the stage of organizational founding.

Transaction Cost Theory

Focusing on firm boundaries, transaction cost theory aims to answer the question of when activities would occur within the market and when they would occur within the firm (Williamson, 1991). More specifically, transaction cost theory predicts when the governance forms of hierarchies, markets, or hybrids (e.g., alliances) will be used. Williamson, who was recognized with a Nobel Prize for his work on transaction costs, theorized that whether activities would be internalized within a firm depended on their transaction costs. He saw transactions broadly as transfers of goods or services across interfaces, and argued that when transaction costs were high, internalizing the transaction within a hierarchy was the appropriate decision. Conversely, when transaction costs were low, buying the good or service on the market was the preferred option. Three dimensions were developed for characterizing transactions: uncertainty, frequency, and asset specificity, or the degree to which transaction-specific expenses were incurred. Transaction cost theory is built on assumptions of bounded rationality and opportunism, defined as self-interest with guile.

A review of the empirical literature on transaction cost theory concluded that findings regarding asset specificity were generally supportive of the theory, while findings for uncertainty were mixed (David and Han, 2004). Although only a small number of studies focused on the frequency of transactions, those studies were generally supportive of the theory. David and Han (2004) further concluded that considerable empirical support existed for predictions about hierarchies versus markets, but less support existed for predictions about the choice of hybrids over markets or hierarchies.

A debate has raged in recent years about whether transaction costs or organizational capabilities are the most important determinants of firm boundaries. Emphasizing the importance of capabilities, researchers have argued that firms internalize activities that they perform with greater capability than external providers (Jacobides and Winter 2005). This debate connects transaction cost theory to the BTOF and evolutionary theory because organizational learning, which figures prominently in those theories, contributes to the development of routines and organizational capabilities.

Recent theorizing in transaction costs includes capabilities as well as transaction costs as determinants of whether firms internalize activities. For example, Argyres and Zenger (2012) noted that transaction costs and capabilities are intertwined over time: past governance decisions affect the development of current capabilities, and current capabilities affect future governance decisions. Current research focuses on articulating the relationship between capabilities and transaction costs.

Discussion

Behavioral theories of organizations – in plural – are important for understanding how organizations actually work, and they represent the bulk of empirical work performed on this topic. We are unable to give a full review within a manageable number of pages, but we have given a taste of the work. The range of topics is wider than our table suggests, although new organizations and forms, forming goals and establishing tasks, motivating members, dividing and coordinating tasks, and learning and adaptation are still an impressive list of organizational problems. Likewise, the behavioral theory of the firm, evolutionary theory, population ecology, institutional theory, and transaction cost theory are important lines of investigation under the umbrella of behavioral theories of organizations, but they are not the only ones.

Although this field of research is too large and fast moving to make the identification of trends easy, we have observed that theories that start out behavioral remain so, and theories that initially have little behavioral content incorporate it over time. The behavioral concepts of organizational learning and knowledge transfer have been central to the BTOF and evolutionary theory since their inception and remain central, and these concepts are playing increasing roles in population ecology, institutional theory, and transaction costs theory. In the population ecology tradition, specific cases of such reasoning include work examining learning from other organizations, including work arguing that the transfer of routines from parent firms contributes to the success of their progeny. In institutional theory, early work on the diffusion of institutional practices emphasized their symbolic value, but recent work includes considerations of goal-oriented behavior that aligns the reasoning with behavioral theory. Transaction costs researchers acknowledge that an organization's capabilities, which are developed by learning from experience, affect decisions about whether to internalize tasks.

It is too early to tell the strength of the theoretical movement toward a common ground described here. If it does gain momentum, it will produce a unique result. Research traditions that started out with little relations to each other will coalesce into an overarching field of study joined by an interest in creating behavioral theories of organizations that are informed by ideas of bounded rationality. We think such an outcome would produce an era of dialogue between the different research traditions, to the benefit of our understanding of organizations.

Abstract

According to just world research, people need to believe that they live in a world in which everyone gets what they deserve and deserves what they get. This belief in a just world is conceptualized as an interindividually varying disposition and has important adaptive functions. The stronger this belief is, the more people trust in justice and the more they defend justice in the world, either behaviorally or cognitively, and the better their well-being is.

Conceptualization of the Belief in a Just World

Societies are full of inequalities and injustices – the uneven distribution of wealth or the inequality of access to health care and education to name just a few. Individuals react differently to observed or experienced injustice. Some feel moral outrage and seek to restore justice (e.g., Montada et al., 1986). Others show disdain for the victims (for a review, see Lerner and Miller, 1978) or adopt belief systems that serve to justify existing social, economic, and political arrangements (Jost et al., 2004). In other words, people confronted with injustices restore justice in reality or they may try to restore injustices – that are difficult to redress in reality – cognitively by blaming the victim or justifying the status quo. The more people believe in a just world the more they care for justice.

The Just World Hypothesis

Several psychological theories propose explanations for justice-driven reactions. One of the most influential is the just world hypothesis introduced by Lerner (e.g., Lerner and Simmons, 1966). The just world hypothesis states that people need to believe in a just world in which everyone gets what they deserve and deserves what they get. This belief enables them to deal with their social environment as though it were stable and orderly and thus serves important adaptive functions. As a result, people are motivated to defend their belief in a just world when it is threatened by injustices, either experienced or observed. If possible, justice is restored in reality (e.g., by compensating victims). If the injustice seems unlikely to be resolved in reality, however, people restore justice cognitively by reevaluating the situation in line with their belief in a just world. This cognitive process is called the assimilation of injustice.

This just world dynamic was first evidenced by Lerner and Simmons (1966). These researchers confronted their participants with an 'innocent victim,' a young woman participating in a learning task who was punished for each mistake by being administered seemingly painful electric shocks. When led to believe that the experiment would continue in the same way, the participants showed disdain for the victim on an adjective measure; when led to believe that the victim would be compensated for the pain of the electric shocks by receiving money for each correct answer in a second part of the experiment, they stopped disdaining the victim. Finally, nearly all participants who were given the choice between continuing the shock condition and switching to the compensation condition voted for the latter. Note, however, that merely voting to award the victim compensation did not stop participants from derogating the victim. It was only when they were certain that compensation would be given that the injustice was no longer assimilated. This innocent victim paradigm remains the most influential in modern experimental just world research; it is only the type of innocent victim that has changed (e.g., Correia et al., 2007). In sum, the confrontation with an innocent victim triggers a motivation to restore justice.

The Belief in a Just World as a Disposition

A substantial amount of research on belief in a just world has been experimental in nature (for a review, see Hafer and Bègue, 2005), focusing primarily on the maladaptive functions of the belief in a just world, such as disdain for the victim. Since the 1970s, however, another strand of research has examined individual differences in the belief in a just world and found that it also serves important adaptive functions (for a review, see Furnham, 2003). This research agenda was triggered by the introduction of the first belief in a just world scale by Rubin and Peplau (1973), which assessed individual differences in the belief that the world is generally a just place. This approach allowed the role of the belief in a just world to be investigated within the framework of personality dispositions, and positive associations were found particularly with authoritarianism and internal locus of control (for a review, see Furnham and Procter, 1989).

Since the 1990s, more studies have investigated the positive as well as the negative social consequences of the belief in a just world, and the focus of these investigations has been extended to cover the consequences of holding a belief in a just world for the believers. Based on suggestions originating from earlier research (e.g., Furnham and Procter, 1989), these studies have shown that it is necessary to distinguish the belief in a personal just world, in which one is usually treated justly, from the belief in a general just world, in which people in general get what they deserve (e.g., Dalbert, 1999). In line with the self-serving bias in general and in fairness reasoning in particular (Messick et al., 1985), research evidenced that people tend to endorse the personal more strongly than the general belief in a just world and that the two constructs have a different meaning. The personal belief in a just world is a better predictor of adaptive outcomes (e.g., subjective well-being), and the belief in a just

world in general is a better predictor for example of harsh social attitudes (e.g., Bègue and Muller, 2006).

Of course, other differentiations of the just world construct have also been proposed. For the general just world belief, e.g., a general belief in immanent justice has been distinguished from a general belief in ultimate justice, and a general belief in distributive justice has been distinguished from a general belief in procedural justice (e.g., Lucas et al., 2007). Finally, the general belief in a just world has been differentiated from the general belief in an *un*just world (Dalbert et al., 2001). This latter research showed that general belief in a just world should not be seen as a bipolar construct, but as a two-dimensional one. However, the differentiation between a more general and a more personal just world belief thus far seems to be the most widespread and well-examined distinction. Thus, the present summary focuses on research on general and personal just world beliefs.

Belief in a Just World and Other Personality Dispositions

One of the first associations observed between the belief in a just world and other personality dispositions was the positive correlation between just world belief and religiosity (e.g., Rubin and Peplau, 1973). Research on the differences between the two has confirmed that they are distinct dispositions, and cross-cultural research has found few differences in the just world belief across cultures with contrasting religious and political backgrounds (e.g., Furnham, 1993). A positive and sometimes substantial association has also been found between authoritarianism and just world belief (for a review, see Furnham and Procter, 1989). Analyses of the common factor structure of the two constructs support the two-factor hypothesis and their differential meaning, with the belief in a just world providing a more positive outlook than authoritarianism (e.g., Dalbert, 1992). The positive associations repeatedly observed between just world belief and internal locus of control have prompted speculation about an overlap between these two constructs as well (for a review, see Furnham and Procter, 1989). The two constructs should be distinct from a theoretical perspective, however. The belief in personal agency is consistent with the belief in a just world as long as the justice principle endorsed is the equity norm. Other ideas of justice (e.g., the equality or the need principle of justice or the belief in a just God) are not consistent with the belief in internal control. Finally, there is some evidence to suggest that the belief in a just world as a personality trait is correlated with global personality dimensions. In particular, empirical findings indicate a negative relationship between just world belief and neuroticism, consistent with the positive outlook that the belief in a just world provides (e.g., Lipkus et al., 1996). Nevertheless, studies controlling for neuroticism evidenced the incremental validity of the just world belief (e.g., Dalbert and Dzuka, 2004). Taken collectively, research supports the differential validity of the belief in a just world within the network of personality dispositions.

Justice Motive versus Justice Motivation

In the context of just world research and theory, scholars often speak of the justice motive (e.g., Ross and Miller, 2002). The shift from the experimental to the individual differences approach to the belief in a just world made it necessary to differentiate between a justice motive and justice motivation. Motives are individual dispositions reflecting individual differences in the tendency to strive for a specific goal. A justice motive is thus an individual disposition to strive for justice as an end itself. According to Lerner (1977), the individual belief in a just world can be interpreted as an indicator of such a justice motive. The belief in a just world indicates a personal contract; the more people want to rely on being treated justly by others, the more obligated they should feel to behave justly themselves. Thus, the stronger the belief in a just world is, the stronger the justice motive.

Experimental just world research typically does not assess individual differences, however, but interprets experimental reactions in the light of just world reasoning. Such research thus addresses justice motivation, and not the justice motive as an individual differences disposition. Motivation can be defined as a person's orientation toward a specific goal in a specific situational state; thus, justice motivation means the orientation toward justice in a given situation. Justice motivation is triggered by specific situational circumstances in interaction with personal dispositions. In the case of justice motivation, that personal disposition may be the justice motive or other dispositions (e.g., Lind and van den Bos, 2002). As an extension of this reasoning, belief in a just world is an indicator of a justice motive; justice motive theory (Dalbert, 2001) moreover perceives it as an implicit justice motive that operates on an intuitive level of information processing and predicts intuitive reactions to injustice (for a review, see also Hafer and Bègue, 2005).

Consequences of the Belief in a Just World

Today belief in a just world represents a disposition that can easily be measured. Thus, a growing number of research in the last decade was able to show important consequences of that belief. In line with justice motive theory, this research indicates that belief in a just world leads to intuitive justice-driven reactions as the striving for just behavior and the avoidance of unjust behavior, assimilation of injustice, and trust in justice. Therefore, belief in a just world serves adaptive functions and can thus be seen as a resource that sustains subjective well-being (Dalbert, 2001).

Belief in a Just World and Social Behavior

In a just world, a positive future is not the gift of a benevolent world, but a reward for the individual's behavior and character. Consequently, the more individuals believe in a just world, the more compelled they should feel to strive for justice themselves. The just world belief is thus indicative of a personal contract (Lerner, 1977), the terms of which oblige the individual to behave justly. Therefore, strong just world believers are more likely to help people in need (Bierhoff et al., 1991), at least as long as the victims are seen as 'innocent' or as member of the in-group (e.g., Correia et al., 2007). In addition, the belief in a just world has been shown to be one of the important correlates of social responsibility (Bierhoff, 1994), commitment to just means (e.g., Hafer, 2000), and, inversely,

delinquent and cheating behavior (e.g., Donat et al., 2013), and bullying behavior (e.g., Donat et al., 2012). Moreover, the obligation for reciprocity has been found to be stronger among individuals with a strong just world belief (Edlund et al., 2007). Finally, a laboratory study revealed that own unjust behavior is censured by a decrease in self-esteem only for those with a strong belief in a just world (Dalbert, 1999).

Belief in a Just World and the Assimilation of Injustice

When individuals with a strong just world belief experience an injustice that they do not believe can be resolved in reality, they try to intuitively assimilate the experience to their just world belief. This can be done for example by justifying the experienced injustice as being at least partly self-inflicted, by playing down the injustice, by avoiding self-focused rumination, or by forgiving (e.g., Dalbert, 1997). As a result of these mechanisms, positive relationships have been observed between the belief in a just world and justice judgments in various domains of life. Most research into this assimilation has dealt with blaming the victim and justice judgments.

Blaming the Victim

A wealth of evidence from traditional research into the just world construct shows that individuals confronted with injustice are motivated to defend their just world belief. When observers are given the opportunity to adequately compensate an 'innocent' victim (e.g., Berscheid and Walster, 1967) and thus restore justice in reality, nearly all choose to do so (Lerner and Simmons, 1966). If they are not in a position to secure compensation for the victim, observers tend to defend their belief in a just world by psychological means. Two of these means have been examined in detail in just world research. Observers can either show disdain for victims, reasoning that their fate is a deserved punishment for a bad character (characterological attribution), or they can blame victims for having inflicted their fate upon themselves – after all, a self-inflicted fate is not unjust (behavioral attribution). Just world research has shown that observers prefer to blame the victim rather than to show disdain. The more a fate is seen as self-inflicted, the less disdain is observed (e.g., Lerner and Matthews, 1967). In sum, when people are confronted with the victim of an unjust fate, blaming the victim seems to be a crucial element in the defense of their belief in a just world.

Similar mechanisms can be assumed to operate for the victims of injustice themselves. Comer and Laird (1975) have shown experimentally that internal attributions seem to be a way of reevaluating one's fate as just. The significance of causal attributions, and especially of internal attributions, has thus been a subject of much discussion in the context of the just world hypothesis (e.g., Lerner and Miller, 1978). People with a strong just world belief are expected to be motivated to defend their belief by making internal attributions of negative outcomes, thus maintaining their subjective well-being. Although some research evidenced the hypothesized positive association between just world belief and internal attributions of the victims themselves (e.g., Hafer and Correy, 1999), other studies found no association between them (e.g., Fetchenhauer et al., 2005). Overall, the pattern of results for the belief in a just world and victims' internal attribution is rather mixed.

Justice Judgments

As a consequence of the assimilation process, individuals with a strong just world belief are expected to evaluate observed events and events in their own life as being more just. For example, school students with a strong belief in a just world have been found to be more likely to evaluate their school grades and their teachers,' peers,' and parents' behavior toward them as just (e.g., Peter and Dalbert, 2013), and feel less excluded from school (Umlauft et al., 2013). Similarly, prisoners with a strong personal just world belief were more likely to evaluate the justice of the legal proceedings leading to their conviction, the treatment by their prison officers, and decisions on prison affairs as more just (e.g., Dalbert and Filke, 2007).

The personal just world belief is usually seen as a personal disposition, but results indicating an additional, reverse effect of justice experiences on the belief in a just world qualify this assumption. Research has shown that justice experiences in the school and the family modify the personal just world belief (Dalbert and Stoeber, 2006), and factors such as length of imprisonment (Otto and Dalbert, 2005), monotony at work, and mobbing experiences at work (e.g., Dzuka and Dalbert, 2007) are negatively related to the personal just world belief. Thus, the belief in a personal just world must be seen as a partly experiential construct. Nevertheless, an unambiguous pattern of results clearly indicates that a strong personal just world belief leads to events being evaluated as just. Cubela Adoric and Kvartuc (2007) have suggested that injustice experiences only impact the belief in a just world when they reach a specific degree of adversity. Further studies are needed to determine under which conditions the just world belief fosters the assimilation of injustice and under which conditions injustice can no longer be assimilated, but instead undermines the belief in a just world and leads to adverse consequences as embitterment (Dalbert, 2010).

Belief in a Just World and the Trust in Justice

People with a strong belief in a just world are thought to be confident in being treated justly by others, and it is this trust in particular that is hypothesized to give the just world belief the character of a resource in everyday life. Assuming that people get what they deserve, they will be punished for deceiving others. Accordingly, in a just world, people are expected to be honest with one another, and people who have been deceived may conclude that they deserved it in some way. It can thus be hypothesized that people with a strong just world belief prefer not to think they have been deceived or taken advantage of. In line with this reasoning, research has shown a positive association of just world belief with general interpersonal trust (e.g., Bègue, 2002), trust in societal institutions (Correia and Vala, 2004), and young adolescents' trust in the justice of their future workplace (Sallay, 2004). This trust in future justice has a number of implications.

Risk Perception

Individuals with a strong just world belief are convinced that good things happen to good people and bad things happen to bad people. Because individuals tend to think of themselves as good people (e.g., Messick et al., 1985) the belief in a just world can be expected to give them an optimistic outlook on the

future. This buffering effect is expected to be particularly evident when people are threatened by injustice. Lambert et al. (1999) were the first to study the meaning of the belief in a just world for risk perception and showed that the just world belief seems to enable fearful individuals (i.e., those high in authoritarianism) to be confident of avoiding an unjust fate. It is particularly important for individuals exposed to external risks – i.e., those perceived to be controlled by others or by fate (e.g., robbery) – rather than to internal risks – i.e., those that are under their personal control (e.g., suicide) – to be able to rely on the environment being just. Indeed, Dalbert (2001) found that the buffering effect of the just world belief for fearful individuals held only for external risks, and not for internal risks. Finally, Hafer et al. (2001) found that individuals with a strong just world belief, but low in interpersonal control, seem to put themselves at greater risk, presumably as a consequence of a lowered risk perception. In sum, just world belief appears to function as a buffer against the perception of external risk for those who tend to need such a buffer, but this mechanism may result in higher exposure to risks in reality.

Investment in One's Future

The belief in a just world enables individuals to rely on their good deeds being rewarded at some point in the future. The certitude that everyone will ultimately get what they deserve encourages individuals to invest in their future. In contrast, those who do not believe in a just world doubt the value of such an investment, because the return on it is uncertain. Zuckerman (1975) was the first to observe that people with a strong just world belief may choose to invest in their future, when in a state of need to trust in the justice of their own future. Hafer (2000) corroborated these findings and demonstrated experimentally that individuals with a particular need to believe in a bright future defended their just world belief more strongly in the face of threat. In the same vein, questionnaire studies with students facing the school-to-work transition (Dette et al., 2004), young male prisoners (Otto and Dalbert, 2005), and young adults living in assisted accommodation (Sutton and Winnard, 2007) have shown that just world belief is positively associated with confidence that personal goals will be attained.

Achievement

Individuals with a strong belief in a just world show more trust in their future and in others' behavior toward them. It is thus hypothesized that they expect to be confronted with fair tasks in achievement situations, and for their efforts to be justly rewarded. They can thus be hypothesized to feel less threatened and more challenged by the need to achieve, to experience fewer negative emotions, and to achieve better results. Tomaka and Blascovich (1994) conducted a laboratory study to test the basic hypotheses outlined above and confronted their participants with two rapid serial subtraction tasks. Participants with a strong just world belief felt more challenged and less threatened, and performed better than those with a weak belief.

Extending this laboratory research to the school and work setting, studies have revealed a positive correlation between just world belief and school achievement, and self-rated performance at work (e.g., Kahileh et al., 2013). Finally, Allen et al. (2005) have observed that nations whose citizens have stronger just world beliefs show a faster pace of workforce modernization and GNP/capita growth.

Belief in a Just World and Subjective Well-Being

Because the main properties of the belief in a just world – indicating commitment to a personal contract, endowing trust in the justice of the world, and providing a framework for the interpretation of the events in one's life – have a variety of adaptive implications, the belief in a just world can be expected to positively impact subjective well-being, either directly or indirectly, mediated by these implications. There is ample evidence of a positive relationship between just world beliefs and subjective well-being. Moreover, research has shown that the belief in a personal just world is more important than the general just world belief in explaining well-being (e.g., Otto et al., 2006), and that this positive association between just world belief and well-being is true for nonvictims (e.g., Dzuka and Dalbert, 2006) and various groups of victims (e.g., Otto et al., 2006). In addition, Dzuka and Dalbert (2007) demonstrated that teachers' well-being was positively associated with their belief in a just world and that this relationship held when exposure to student violence was controlled. This study is one of the few to have found evidence for a buffering effect of the just world belief: It was only among teachers with a weak just world belief that exposure to violence was associated with more negative affect; exposure to violence did not explain negative affect among those with a strong just world belief.

A personal resource can be defined as a personal disposition that helps people to cope with the events of their daily life. The stronger the resource, the better equipped they are to cope. A personal resource thus implies a main effect hypothesis. A personal buffer, in contrast, is usually seen as a resource that takes effect only under specific adverse conditions. A buffer thus implies a moderator hypothesis and it moderates the association between strain and outcome. Overall, research findings are very much in line with the resource hypothesis and do not support the buffer hypothesis. The just world belief should thus be seen as personal resource helping to sustain the well-being of people of all ages in diverse situations, victims and nonvictims alike.

Conclusion

Just world research has shown that people need to believe in justice, and that they strive for justice in order to maintain their basic belief in a just world (e.g., Lerner and Miller, 1978). This justice motive is reflected by an interindividually varying belief in just world and this disposition explains the differences in people's striving for justice as an end in itself, including their own behavior and assimilation of observed or experienced injustices. In return, the justice motive endows trust in the justice of the world and in being treated justly by others.

The basic idea of the just world hypothesis is that people confronted with injustices suffer and feel the unconscious need to restore justice (e.g., Lerner and Simmons, 1966). As a consequence, the belief in a just world particularly impacts intuitive justice-driven reactions such as, for example, the assimilation of injustice. Thus, research suggests that the belief

in a just world is an essential but unconscious source of responses to injustice, in line with the role of other implicit human motives (McClelland et al., 1989). Justice motive theory (Dalbert, 2001) thus interprets the belief in a just world as indicating an implicit justice motive. Lerner and Goldberg (1999) argue that conscious and intuitive justice-driven reactions coexist, and may be elicited simultaneously in the same situation. The belief in a just world seems to operate on an unconscious level and can thus be expected to better explain intuitive than conscious reactions to injustice (Dalbert, 2001). Important challenges for future research on the just world construct include integrating just world research within such a broader framework of human motives and differentiating between the explanation of more controlled versus more intuitive justice-driven reactions in the light of just world reasoning.

Abstract

'Belief,' along with 'believe, beliefs,' and 'belief systems,' has served as a kind of 'odd job' word for anthropologists: a word commonly used for the analysis of a society's culture, religion, or ideas about the world, but seldom defined or explicitly theorized. Belief is often included in omnibus definitions of culture, such as Tylor's classic "Culture, or civilization, … is that complex whole, which includes knowledge, belief, art, law, morals, custom, and any other capabilities and habits acquired by man as a member of society" (1871, from Kroeber and Kluckhohn, 1952, p. 43) or Sapir's "culture, that is, … the socially inherited assemblage of practices and beliefs that determines the texture of our lives …" (1921, Kroeber and Kluckhohn, 1952, p. 47). The term often refers explicitly to religion, as in Tylor's minimum definition of religion as 'the belief in Spiritual Beings' (1873), but is used equally for claims people make about the empirical world or their social institutions.

Accounts of central tenets of culture or worldview in a society are often reported as beliefs. Lawrence's (1964) discussion of cargo cults in New Guinea is typical: "The Ngaing believed that their world was brought into being by their deities" (p. 16); "all these peoples believed in a creator God" (p. 21); "the natives believed they could obtain cargo … largely by ritual" (p. 235). As Needham (1972, p. 3) points out, Lawrence did not find it necessary to define belief or describe how he knows "that men in New Guinea believe what they say"; he simply assumed that this "psychological category in the English language denotes a common human capacity." This is typical of anthropological writing at the time. Despite its ubiquity, 'belief' seldom appears in the Index of ethnographies, and the *International Encyclopedia of the Social Sciences* (Sills, 1968) has no entry for Belief, simply referring the reader to '*see* Attitudes; Myth and Symbol; Religion, Anthropology of; Values.'

Despite a long history of analyzing other societies through a systematic description of their 'beliefs and behaviors,' by the 1980s ethnographic accounts had begun to reflect ironically on belief as a shifting anthropological category. "Take an ethnographer," writes Jean Favret-Saada (1980, p. 4):

> She has spent more than thirty months in the Bocage in Mayenne, studying witchcraft … 'Tell us about the witches,' she is asked again and again when she gets back to the city … confirm that *out there* there are some people who can bend the laws of causality and morality, who can kill by magic and not be punished; but remember to end by saying that they do not really have that power: they only believe it because they are credulous, backward peasants … No wonder that country people in the West are not in any hurry to step forward and be taken for idiots …

Favret-Saada concludes: "To say that one is studying beliefs about witchcraft is automatically to deny them any truth: it is just a belief, it is not true."

'Belief' is thus a ubiquitous term in much of the anthropological corpus, a commonsense category used for the analysis of the tenets of culture or religion. It is, however, a term that is increasingly contested, and its use has declined significantly in favor of focus on practice, narrative, and metaphor. A review of the meaning and history of the term belief is needed to make sense of its complex genealogy in anthropological usage.

Defining 'Belief'

The Oxford English Dictionary (1989) defines 'belief' as:

1. The mental action, condition, or habit, of trusting to or confiding in a person or thing; trust, dependence, reliance, confidence, faith.
2. Mental acceptance of a proposition, statement, or fact, as true, on the ground of authority or evidence …
3. The thing believed; the proposition or set of propositions held true …

Hahn (1973, p. 208) attempts to clarify anthropological understandings of belief, defining beliefs as "general propositions about the world (consciously) held to be true." Tooker (1992, p. 808) points out that such anthropological conceptions of belief typically have two elements: 'propositionality' ('a mental state or conviction in which a doctrine or proposition concerning one's worldview is affirmed as true as opposed to false') and an assumption that such a 'prepositional relationship to tradition is an 'interiorized' one because of its reference to mental states.'

The *OED* indicates that the definition of belief as a proposition held to be true, a definition apparently taken over by anthropologists, rests on an older definition of belief as the condition of trusting in a person or thing, as 'faith.' At the same time, while a 'belief' is defined as a 'mental acceptance of a proposition … as true,' Favret-Saada and others suggest that describing a proposition as a 'belief' implies doubt or even falsehood, that "studying beliefs about witchcraft is automatically to deny them any truth." A review of the history of the semantics of 'belief' suggests that this complexity is grounded in changes in the meaning and use of the terms 'believe' and 'belief' in English (and their counterparts in other European languages).

A History of 'Belief' in Euro-American Language Use

Anthropologists often talk with members of other societies about some aspect of 'their' world which does not exist in 'ours' and which anthropologists are comfortable asserting is not part of empirical reality. An examination of anthropological texts suggests that such phenomena – the witches of the Bocage or

the Azande, the 'cargo' of the Papua New Guinea cults – are discussed in the language of belief – and that the beliefs of others are juxtaposed to 'our' knowledge of the empirical world (see Good, 1994, Chapter 1). Western civilization has long given great importance to 'beliefs,' with wars, church schisms, persecutions, and martyrdom revolving around credos and demands for the renunciation of false beliefs. How is it that this same term, 'belief,' came to be so central to anthropological analysis, and what is implied by the juxtaposition of belief and knowledge?

The richest discussion of the history of the concept belief is to be found in two books by Wilfred Cantwell Smith, the historian of religion, which explore the relation between 'belief' and 'faith' historically and across religious traditions. Through historical and linguistic analysis, Smith comes to the startling conclusion that "the idea that believing is religiously important turns out to be a modern idea," and that the meaning of the English words 'to believe' and 'belief' have changed dramatically, since around 1700, leading to misunderstanding of both the Christian tradition and the religious faith of others.

Smith demonstrates that the Old English words that evolved into the modern 'believe' (*geleofan*, *geliefan*) meant 'to belove,' 'to hold dear,' 'to cherish,' 'to regard as lief,' and reflect the Latin root *libet*, 'it pleases,' or *libido*, 'pleasure' (Smith, 1977, pp. 41–46; Smith, 1979, pp. 105–127). In Chaucer's *Canterbury Tales*, the words 'accepted by bileve' mean simply "accept my loyalty; receive me as one who submits himself to you." Thus, Smith argues that "belief in God" originally meant "a loyal pledging of oneself to God, a decision and commitment to live one's life in His service" (Smith, 1977, p. 42). Its counterpart in the medieval language of the Church and in the Credo was "I renounce the Devil," belief and renunciation being parallel and contrasting performatives or actions, rather than states of mind. Today, however, Smith argues, the ritual acclamation "I believe in God" means for many people "Given the uncertainty as to whether there be a God or not, as a fact of modern life, I announce that my opinion is 'yes, I judge God to be existent" (1977, p. 44).

Smith argues that this change in the language of belief can be traced in the grammar and semantics of English literature and philosophy, as well as in popular usage. Three changes serve as indicators of the changing semantics of the verb 'to believe.' First, Smith finds that grammatically, the *object* of the verb 'to believe' shifted from a person (whom one trusted or had faith in), to a person and his word (his virtue accruing to the trustworthiness of his word), to a proposition. This latter shift began to occur by the end of the seventeenth century, with Locke, and was firmly represented by the mid-nineteenth century in John Stuart Mills' philosophy (Smith, 1977, p. 48). The twentieth century has seen a further shift, as beliefs have come to mean 'presuppositions,' and it was in this sense that 'belief systems' became nearly synonymous with 'culture' in some strands of anthropology (see Black, 1973).

A second shift has occurred in the *subject* of the verb 'to believe,' from an almost exclusive use of the first person – 'I believe' – to the predominant use of the third person, 'he believes' or 'they believe.' In anthropology, the impersonal 'it is believed that' parallels the discussion of culture as belief system or system of thought. This change in subject subtly shifts the nature of the speech act involved – from existential or performative ('I believe') to descriptive ('the Ngaing believe that').

Third, Smith observes that an important and often unrecognized change has occurred in 'the relation of belief to truth and knowledge,' as these are historically conceived. Bacon wrote in 1625 of "the belief of truth," which he defined as the "enjoyment of it." Belief maintains its sense here of holding dear, of appropriating to oneself that which is recognized as true. By the nineteenth century, however, 'to believe' had come to connote doubt, and today it suggests outright error or falsehood. Knowledge requires both certitude and correctness; belief implies uncertainty, error, or both. Smith's favorite illustration of the juxtaposition of belief and knowledge is an entry in the Random House dictionary which defines 'belief' as "an opinion or conviction," and at once illustrates this with 'the belief that the earth is flat'! It is virtually unacceptable in popular English usage to say that members of some society 'believe' the earth is round; if this is part of their worldview, then it is knowledge, not belief.

Smith goes on to argue that failure to recognize this shift in meaning has led to mistranslation of texts in the Christian tradition and ultimately to 'the heresy of believing,' the deeply mistaken view that belief in this modern sense is the essence of the religious life rather than faith. Equally important, for Smith, the misplaced focus on belief as the primary dimension of religious life has led to mistranslations and misunderstandings of other religious traditions. It is this claim that has special relevance for anthropology.

'Beliefs' and 'Believing' in Diverse Anthropological Traditions

The term 'belief' functions quite differently in diverse anthropological traditions. A brief review of several traditions will indicate why 'belief' has emerged as a contested term in recent anthropological writing.

The Intellectualist Tradition and Rationality Debates

'Beliefs' and 'rationality' are central terms in the Intellectualist tradition most closely associated with E.B. Taylor and J.G. Frazer, as well as with a series of 'Neo-Tylorians' and a set of rationality debates in the 1970s and 1980s. Tylor and Frazer set out to trace the evolution of beliefs from our 'rude forefathers' to the present, investigating forms of rationality, errors in reasoning, and the history of the evolution of culture from magic to religion and the emergence of science. An example from Frazer's Gifford Lectures, published as *The Belief in Immortality* (Frazer, 1913), will illustrate the logic of this program, as well as the evolutionist language that led to its rejection:

> … the question of the validity or truth of religious creeds cannot, perhaps be wholly dissociated from the question of their origin. If, for example, we discover that doctrines which we had accepted with implicit faith from tradition have their close analogies in the barbarous superstitions of ignorant savages, we can hardly help suspecting that our own cherished doctrines may have originated in the similar superstitions of our rude forefathers; … The doubt thus

> cast on our old creed is perhaps illogical, since even if we should discover that the creed did originate in more superstition, … this discovery would not really disprove the beliefs themselves, for it is perfectly possible that a belief may be true, though the reasons alleged in favor of it are false and absurd …

Beliefs in this tradition were investigated as rational propositions and forms of explanation for natural and religious phenomena. The intellectualist paradigm was grounded in philosophical empiricism, and judgments concerning validity of propositions and the evolution of explanatory frames from those which were false, even absurd, to those which correctly represent the natural world were essential to the analysis.

British structural–functionalism explicitly rejected the search for origins, the evolutionary claims, and the focus on individual beliefs and their rationality as a basis for social analysis. Nonetheless, classic texts, such as Evans-Pritchards' *Witchcraft, Oracles and Magic among the Azande* (1937) maintained the basic structure of inquiry, investigating witchcraft as a form of rational explanation for misfortune and distinguishing those explanations which attribute 'supra-sensible qualities' to phenomena (described as beliefs) from those which accord to contemporary science (described as knowledge) (cf Good, 1994, pp. 11–13).

In the 1970s and 1980s, the intellectualist tradition was revived in British anthropology under the rubric of Neo-Tylorianism and the rationality debates (e.g., Wilson, 1970; Hollis and Lukes, 1982). Reacting to the perceived vacuousness of functionalist explanations, a group of anthropologists returned to investigations of the rational structure of non-Western religious systems and their similarities to science as systems of explanation for the natural world. At the heart of these debates was a central question: "when I come across a set of beliefs which appear prima facie irrational, what should be my attitude toward them?" (Lukes, 1970, p. 194). For example, "what does one do with the exotic utterances of primitives, who may say such things as 'my brother is a cockatoo,'" asks Turner (1979, p. 401). "Some things, such as a flat contradiction, could not be 'believed,' in any useful sense of 'believe.' … Can the fact that these utterances cannot be translated into anything that we would call 'rational' warrant a claim that, e.g., these primitives possess a non-logical mentality?" 'Beliefs' in this paradigm were understood as rational propositions, held to be true by members of a society, and analysis focused on the identification, translation, and rational structure of belief systems, examining characteristics of systems 'open' to falsification, and thus to change, in contrast to 'closed systems,' which remain impervious to contradictory data that would lead to change and evolution in the direction of more rational explanation. Needham (1972), however, criticized this view of belief, arguing that belief lacked cross-cultural equivalents. His empiricist perspective also suggested that anthropology has no tools by which to know if informants actually believe what they report to believe. Despite his rejection of the concept, his criticism maintains a separation between belief and knowledge, holding belief as having only an incidental relationship to the known or knowable.

Structural Functionalism

Reacting against intellectualists' search for origins and focus on individual states of minds, Radcliffe-Brown and generations of British anthropologists placed investigations of the structure of social institutions at the center of anthropological theorizing. In this context, individual beliefs are of little interest, and a focus on the relationship between rational propositions and the natural world is replaced by an interest in the structural relation between the symbolic and the social order. Leach made this explicit: "To ask questions about the content of beliefs which are not contained in the content of ritual is nonsense … Ritual action, and belief are alike to be understood as forms of symbolic statement about the social order" (1954, p. 14).

The Boasian Tradition

Inheritors of the German philosophical romantics' theorizing about culture and its *Geist*, American anthropologists of the Boasian tradition were more interested in the 'spiritual possessions of the group rather than the individual' (Sapir, 1924, p. 405), in the role of language and culture in constituting phenomenal experience and the 'behavioral environment' (Hallowell, 1955) of members of a society. Although the term 'belief' appears in this tradition, it has little theoretical salience. Sapir notes this explicitly: " … the cultural conception we are now trying to grasp aims to embrace in a single term those general attitudes, views of life, and specific manifestations of civilization that give a particular people its distinctive place in the world. Emphasis is put not so much on what is done and believed by a people as on how what is done and believed functions in the whole life of that people, on what significance it has for them" ([1924]1970, p. 83). The broad rejection of 'belief' as a common category for cultural analysis carries over into the Geertzian interpretive tradition, into studies of narrative, embodiment, and experience, as well as into the most psychological anthropology, particularly in the American context.

Cognitive Anthropology

The term 'belief' appeared as a core analytic category in American anthropology beginning in the 1950s among anthropologists intent on creating a new, more scientific paradigm for studying culture, who gathered under the banner of 'The New Ethnography,' ethnosemantics, or cognitive anthropology. For cognitivists, "cultures … are not material phenomena; they are cognitive organization of material phenomena. … The object of study is not these material phenomena but the way they are organized in the minds of men" (Tyler, 1969, p. 3). In this tradition, culture is conceived of as generative models, and beliefs are those cognitive structures which take propositional form: "Beliefs are propositions about the relations among things to which those who believe have made some kind of commitment … for pragmatic or emotional reasons" (Goodenough, 1990, p. 597). Although 'beliefs' assume a core analytic function in this tradition, many cognitivists share more with the Boasian tradition than with the intellectualist tradition, in that they are interested in investigating how semantic categories and

linguistic structures shape perception of the phenomenal world rather than in normative claims about rationality. (They differ sharply in methodology and forms of ethnographic writing.) 'Beliefs' and 'knowledge' are often used interchangeably in this tradition, rather than explicitly juxtaposed (see Black, 1973). Nonetheless, the term 'belief' often subtly connotes counterfactuality in this tradition as in others.

Medical Anthropology, Public Health, and Health Psychology

Studies of health beliefs was a key element of early forms of medical anthropology, particularly those devoted to applied work in the public health field, although this has not been true in recent years (see Good, 1994). However, analyses of beliefs about illness etiologies, the risks of particular behaviors, or the benefits of particular treatments are still ubiquitous in public health work and health psychology. Popular or folk health beliefs were explicitly juxtaposed to medical knowledge, and educational campaigns are devoted to correcting mistaken ideas with the hope that this will produce more rational behavior.

A review of recent medical anthropology literature finds this kind of discussion of health beliefs increasingly uncommon. Those who talk about health beliefs tend to do so in an explanatory model format and understand belief as a template for action (Erickson, 2007). Most medical anthropologists today focus instead on narrative, political, and moral economies of health, and experience rather than on health beliefs. Moral anthropology and studies of care giving (Kleinman, 1999, Fassin, 2012) too have moved away from a beliefs-related framework to one which emphasizes personal and social priorities exhibited not by statements of conviction but through practice.

Anthropology of Religion

Although other fields of anthropology have slowly dismissed analyses of belief, anthropology of religion has sustained a healthy debate. Many pick up Needham's skepticism, and question the empirical utility of studying belief (Lindquist and Coleman, 2008). Yet, proponents of belief see it as an opportunity to analyze tensions created by uncertainty, syncretism, and change (Carlisle and Simon, 2012). Convictional belief, for them, becomes a map of action and values in lived experience (Handelman, 2008), and as such a perspective on subjectivity (Simon, 2012). Still others consider convictional belief from Weberian and Durkheimian perspectives focusing on the intellectual and emotional origins and experience of belief, respectively (Lindholm, 2012). Kirsch, however, suggests that belief is best understood as a performative – necessary for ritual efficacy but neither a conviction nor permanent (2004). Engagements with Islam tend to follow Asad and examine practices of piety rather than belief (1993), but this emphasis on practice over convictional belief is not wholesale. Belief as conviction has been a focus of anthropology of religion, but propositional belief seems hard to find, leaving the question of separating knowledge and belief for the faithful to answer.

Critical Reflections

The language of belief has been widely used for ethnographic descriptions of culture, dating back to at least the nineteenth century. In some anthropological traditions it has been a key analytic concept; in others, it has been used infrequently and in a commonsense way. In some of the behavioral sciences, 'beliefs' continues to be used with little self-consciousness. However, in each of these domains, 'beliefs' are explicitly or implicitly juxtaposed to 'knowledge,' and the use of 'believe' or 'beliefs' connotes assertions to be counter to what is 'known' about empirical reality. This is particularly true in fields such as medicine, where the knowledge claims of the natural sciences run headlong into the historicist convictions of anthropology (Good, 1994).

In recent years, the claims implicit in this formulation have been sharply challenged. The representation of others' culture as 'beliefs' ('their' beliefs and 'our' knowledge) authorizes the position and knowledge claims of the anthropological observer. Such authority has been challenged by a variety of forms of critical theory – post-structuralism, feminist writing, postcolonial theorizing, and subaltern studies. The place of the ethnographer as an objective scientific observer, both in research and in ethnographic texts, is increasingly contested, and along with it, the use of the language of 'belief.' At the same time, developments in the history, philosophy, and sociology of sciences challenge any views of science as a progressive, normative 'mirror of nature,' the arbiter between belief and knowledge. As a consequence, the labeling of others' assertions about the world as 'beliefs' is increasingly challenged as pejorative, as failing to recognize the 'local' character of knowledge, and as hegemonic. Thus, although belief is still a word used unreflexively by some, its primacy as a mode of understanding culture, social life, and human action is increasingly uncommon.

Abstract

Daniel Bell's books on social theory, cultural criticism, and political affairs included *The End of Ideology* (1960), *The Coming of Post-Industrial Society* (1973), and *The Cultural Contradictions of Capitalism* (1976). A world-renowned sociologist, he was also recognized as a leader of 'the New York intellectuals,' who began their careers in left-wing movements of the 1930s and achieved prominence by the 1950s as proponents, mostly, of liberal anticommunism. Bell's support of Cold War containment policy and political moderation, alongside his critique of countercultural hedonism, made his work the target of left-wing criticism, which often obscured his actual long-standing social-democratic convictions.

Daniel Bell (10 May 1919 to 25 January 2011) was both a paramount figure in US sociology after World War II and one of the most distinguished 'public intellectuals' of the postwar period. Best known for his description and analysis of 'postindustrial society,' Bell was, earlier, central to the debate over 'the end of ideology,' a common phrase of the 1950s and 1960s citing the apparent decline in the appeal that extreme left-wing and right-wing political doctrines held for Western European and American intellectuals. At the very beginning of his career, he had been an expert labor journalist and an influential historian of American socialism. After his major works had appeared on postindustrial society and what he regarded as the cultural distemper of the 1960s and 1970s, Bell continued to publish essays through the 1980s and 1990s on technological trends, problems of community and civil society, the relation between religion and politics, the nature of modernity and its discontents. His books continued to appear in new editions into the twenty-first century, and his death in 2011 drew widespread attention in the press and eulogies by much younger writers who hailed him as a mentor. His highly nuanced views on politics, morality, culture, and society left his work open to diverse interpretations.

Early Life

Raised in New York City by his mother, a widowed garment worker, Bell spent parts of his childhood in a 'day orphanage' when times were hard or night work kept his mother away from home. An uncle changed the family name from Bolotsky to Bell around the time, in the depths of the Great Depression, that he joined the Young People's Socialist League, youth wing of the Socialist Party (SP). Even at a young age, his political development manifested the kind of idiosyncratic syntheses that always marked his thought: influenced by an anarchist relative who warned him against Bolshevism (and related the Soviet suppression of the Kronstadt sailors' revolt of 1920), Bell veered to the SP's more conservative, anticommunist faction, dominated by an 'Old Guard' of orthodox, evolutionary Marxists historically most hostile to anarchism. Known after 1936 as the Social Democratic Federation (SDF), the Old Guard faction became Bell's political home. Among his mentors was the Russian-Jewish émigré Samuel (Sol) Levitas, who ran the SDF weekly, the *New Leader*, and later introduced Bell to the circle of exiled Mensheviks in New York City, including Boris Nicolaevsky, David Dallin, and Raphael Abramovich.

Attending the City College of New York (which charged no tuition), Bell frequented the gathering places of the student left, where he was familiar with Trotskyists and other dissidents, many of whom held views to the left of his own. With those circles he shared ardent antiwar views, which motivated annual student strikes and rallies for peace in early April (marking the anniversary of the day in 1917 when Woodrow Wilson brought the United States into the European war). His position savored more of pacifist morals (which he recognized in works by the German exile Ernst Toller) than the typical antiimperialism proclaimed by the far left. He moved toward support of US involvement in World War II only after 1940, under the influence of Sidney Hook, the country's leading Marxist philosopher at the time, who had just broken with SP leader Norman Thomas in order to urge US entry on antifascist grounds. Bell's early familiarity with Hook and the City College radicals gave him a firm grounding in Marxism, which remained a permanent deposit in his thought even after he came, roughly by the mid-1940s, to repudiate it. In the meantime, having completed a master's degree in sociology at Columbia University in 1939, Bell also became acquainted with Max Horkheimer and Theodor Adorno, leaders of the Institute of Social Research (Frankfurt) in exile.

Bell's formal academic training ended with his Columbia master's degree. Levitas brought 21-year-old Bell on the *New Leader* staff in summer 1940 and 2 years later made him managing editor. At the paper, Bell astutely balanced his personal allegiance to the anticommunism of the orthodox Old Guard with friendships among more radical young writers (some still part of a diversifying Trotskyist milieu), residual suspicions of the state in war, and links with other political currents ranging from prolabor and middle-class reformers to Dwight Macdonald's emerging antiwar anarchosocialism. Bell's *New Leader* kept up a drumbeat of criticism against American capitalists, first for dragging their feet in the war mobilization, then for fattening on war profits and thus threatening to concentrate corporate power ever more in league with trends toward state centralization. Thus his political views turned slightly leftward again, paradoxically influenced both by the labor agitation that stirred unionist A.

Philip Randolph and the social-democratic economist Lewis Corey to anticipate the postwar creation of a new American labor party and by the hothouse milieu of self-consciously marginal radical-intellectual estrangement from the corporate war regime. He left the *New Leader* for another editing job in 1944, and in 1945 assailed his old newspaper for promoting a 'war-with-Russia' program and helping to fuel what would soon be called the Cold War, which Bell at first called "a paranoid situation where two delusional systems come into conflict" (quoted in Brick, 1986: p. 149).

The war's end marked the beginning of Bell's transition to academic work. Recruited by the economist (and SP activist) Maynard Krueger, he left New York to spend 3 years teaching at the University of Chicago as an instructor in the general-education social science program that David Riesman was helping to shape. Bell moonlighted, teaching US labor history at Roosevelt University, Chicago's city college, and he had some ties, via Edward Shils, with the incipient disarmament milieu around the *Bulletin of Atomic Scientists*. Most of all, the Chicago social science core program attracted young intellectuals for whom social theory and public affairs were assumed to be intertwined; they included Benjamin Nelson, Philip Rieff, Bert Hoselitz, Milton Singer, and Lewis Coser. While he continued to do a bit of political writing, Bell told Dwight Macdonald that his 'ideas are slowly changing,' and by the time he returned to New York in 1948, his compass had shifted: hired to write the 'Labor' column for *Fortune* magazine, Bell also edited for a short time *Modern Review*, a journal led by the Menshevik Raphael Abramovich, worked on a history of American socialism, and took up a lecturer's position in Columbia University's Sociology department (Brick, 1986: pp. 105, 155–157).

The *Fortune* column, which Bell maintained for 10 years, offered vigorous reporting on the big trends in union organizing and labor's relations with corporate business, as well as serving as a study of labor as a social movement. *Modern Review* soon closed, with remarks by Bell on the loss of vitality in the left's intellectual life, while – writing on both politics and social sciences for the new *Commentary* magazine – Bell had staked out an analysis recognizing Harry Truman's election victory on a 'Fair Deal' platform as the sign of a new social and political formula, one in which Business and Labor both had a seat at the table as government frankly fashioned social policy on a national plane, responsive to large institutionalized interest groups but acting at least to some degree in a directive role that was more than a broker. It was a highly modified version of the 'state monopoly capitalism' he had toyed with at the end of the war, but one he now thought showed more promise for enhancing social equity and political inclusion than either Frankfurt School theorists of 'administered society' or his erstwhile friend C. Wright Mills, in his later critique of 'the power elite,' would acknowledge. Here was his verdict, at the conclusion of his first book, *Marxian Socialism in the United States*:

> The old simplistic theories no longer hold. We seem to be evolving toward some form of technical-military-administrative state, especially as the pressures of a permanent war economy bring into focus a priority of needs which are national in character and override the demands of any particular interest group. The growth of a federal budget from four billion in 1930 to more than forty billion in 1950 (apart from the wartime peak of over ninety billion in 1944) was an unplanned and crescive fact, and yet these new enormous magnitudes are of decisive import in shaping the economy. Along the way, the nascent state capitalism has had to enlarge its social budgets and provide for the welfare of large masses; quondam socialists, now in high positions in labor and government, have tended to instill a sense of social responsibility. But it is not primarily a social welfare state which has developed. In the dimly-emerging social structure, new power sources are being created and new social divisions are being formed. Whatever the character of that new social structure may be—whether state capitalism, managerial society, or corporative capitalism—by 1950 American socialism as a political and social fact had become simply a notation in the archives of history.

Thus Bell pronounced his valedictory for the left-wing politics he had known. His history of American socialism, moreover, reflected the Weberian perspective that he, like other young American sociologists of the time, had adopted. Max Weber pinned sociological analysis, as his paramount American exponent, Talcott Parsons, put it, on 'the subjective point of view' of actors: hence it was the mentality or perspective of the socialist movement that drew Bell's attention. Borrowing further from the notion of 'otherworldly asceticism' and from Weber's promotion of an 'ethic of responsibility' in political action as opposed to an 'ethic of ultimate ends,' Bell concluded that American socialism was hobbled, and finally defeated, by its posture of living 'in, but not of the world,' so committed to ideal ends and a misguided moral purity that it could never adapt to practical politics.

The End-of-Ideology Debate

Also, after 1950, Bell helped lead the American Committee on Cultural Freedom (ACCF), the US affiliate of the international Congress for Cultural Freedom (CCF), a liberal anticommunist group intended to rally intellectuals to a common Cold War front against Soviet power and influence. There was some span of opinion among ACCF members, from David Riesman on the 'left' of the group (he resigned, protesting that ACCF had not done enough to defend physicist J. Robert Oppenheimer against red-baiting) to those on the 'right,' like Sidney Hook, who vigorously argued for excluding Communist Party members from teaching positions, and Irving Kristol, who notoriously wrote, "There is one thing that the American people know about Senator McCarthy: he, like them, is unequivocally anti-Communist. About the spokesmen for American liberalism, they feel they know no such thing" (quoted in Pells, 1985: p. 296). Again, Bell occupied a distinctive position on that spectrum. Although friendly with Hook and Kristol, he also collaborated in the mid- and late-1950s with Erich Fromm to promote nuclear disarmament and diplomatic recognition of the People's Republic of China (seeking to defuse Cold War tensions in East Asia), far from conservative views in American life at the time (Friedman and Schreiber, 2013: p. 199).

The CCF's 1955 conference in Milan on 'The Future of Freedom' brought into focus the 'end of ideology,' a theme that had been growing among disenchanted left-wing and liberal intellectuals from the 'discovery of totalitarianism' in the late 1930s to the high pitch of Cold War confrontation in 1950. By

then, Bell, like others, had surrendered his stance of neutrality between 'two delusional systems' and decisively chose to support the world power of the United States and its allies. Writing shortly before the Milan conference, the philosopher of science and conference organizer Michael Polanyi set the tone. His essay in the CCF's English-language organ, *Encounter*, dispensed with the idea that totalitarianism stemmed from economic planning (as free-market 'neo-liberal' Friedrich von Hayek had argued in his 1944 polemic, *The Road to Serfdom*). Rather, Polanyi wrote, totalitarianism arose as a purely political phenomenon when 'civility' (a sense of public responsibility and affective identity nurtured by common traditions) was lacking and when speculative hopes of social reconstruction on a grand scale outran a community's inherited cultural resources. Polanyi was gratified by 'examples of civic reconciliation' in Western Europe since the late 1940s. He noted the signs that "the intensity with which violent political illusions are held had undoubtedly decreased," though he complained that overly excited 'anticapitalists' and 'antisocialists' "are still glaring at each other through the angry masks of obsolete ideologies" (Polanyi, 1955).

Those themes governed the Milan conference. Thus, Edward Shils reported in an essay entitled 'The End of Ideology?' that the last of the doctrinaire formulae in Western politics had indeed fallen: "The full awareness that nationalization is no universal solution to economic problems and that British socialism has not resulted in tyranny have materially weakened the ideologies of thorough-going socialism and thorough-going neo-liberalism" (Shils, 1955). At the same time, Milan signaled a desire among some participants to assuage the ideological passions of the Cold War itself, seeking to make the most of the 'thaw' that appeared possible a few years after Stalin's death. Polanyi argued that the Soviet 'planned economy' in fact functioned "through a system of more or less regulated, and more or less legal, markets." The problems of both world camps were essentially those of a common 'industrial society' (Polanyi, 1955). This was precisely the theme of the conclusion to Raymond Aron's *The Opium of the Intellectuals* (1955), 'The End of the Ideological Age?' Market and plan, Aron wrote, were pure types existing nowhere in reality: "Mixed systems . . . are the normal thing." He wondered why intellectuals still yearned for some abstract, universal truth to realize in action, and he hoped for "the advent of the skeptics" who would "doubt all the models and utopias" (Aron, 1962).

Taking a year's leave from *Fortune*, Bell worked in Paris, 1956–57, planning CCF international seminars on topics like democratic economic planning and the assessment of liberalizing trends in the Soviet Union, as he worked closely with Polanyi, Aron, and C.A.R. Crosland, the leading theorist of 'revisionism' in the British Labor Party. The year's sojourn also secured his personal link to French culture and (centrist) intellectual life, which would lead, years later, to his position as president of the elite Tocqueville Society (1992–2000). His time in Paris coincided with the Hungarian Revolution and suppression of it in fall 1956, and he helped facilitate the escape of dissident intellectuals from the repressive Kadar regime installed by Soviet tanks (Bell, 2000a).

In Bell's judgment, it was the Labor Party's 'New Right' – the current borne by Crosland, Hugh Gaitskell, and Roy Jenkins – that gave the CCF its distinct 'political coloration.' After World War II, Crosland argued in *The Future of Socialism* (1956), "capitalism had been transformed almost out of recognition." Given the reform accomplishments of the post-war Labor government, Crosland claimed, "the dominant emphasis [in public policy] ceases to be on the rights of property, private initiative, competition, and the profit motive; and is transferred to the duties of the state, social and economic security, and the virtues of cooperative action." The demotion of these capitalist standards was complemented by the obsolescence of old, archetypal principles of 'socialism.' Neither more nationalization of production nor complete economic planning at the 'commanding heights' held much conviction among Crosland's like-minded reformers, since high-output mass industry, corresponding mass consumption, Keynesian fiscal management, and fairer norms of meritocracy promised the steady reduction of poverty and a gradual approach to genuine equality of opportunity – a large part of older socialist aims that could be won by nonsocialist, indeed market-based means (Crossman, 1952: p. 42; Crosland, 1957). It was this social-democratic program that informed Daniel Bell's work as it achieved greatest renown following the 1960 publication of *The End of Ideology*. Committed to determinedly moderate reform, he declared that ideologies – totalizing systems of ideas wedded to feverish, mass-based desires for a messianic reinvention of society – had fostered the great calamities of the twentieth century and, thankfully, had now subsided. The same year, Bell's friend Seymour Martin Lipset echoed the theme as a conclusion to his book *Political Man*: "The ideological issues dividing left and right had been reduced to a little more or a little less government ownership and economic planning" (Lipset, 1955, 1960: pp. 170–171).

Both books appeared, fortuitously, at a moment that was believed to open a new era. In his presidential campaign, John Kennedy cleverly seized on the prevailing sense that the 1950s were a sluggish, stolid time and promised rejuvenation and 'Greatness for the Sixties.' Although Bell's antiideological arguments filtered into Kennedy's rhetoric of reform, the coincident surge of civil rights activism and an increasingly vocal 'ban the bomb' sentiment would signal a renewal of dissent reaching a crescendo of protest within a few years. Thus some observers considered Bell and Lipset's 'end of ideology' – insofar as the phrase connoted a historically unique cessation of sharp political conflict between interest groups or between dueling visions of a new future – to be an idea that came 'too late,' obsolete as soon as it appeared in print (Steinfels, 1979: p. 162). Also characteristic of that moment was boom in higher education – the dramatic rise in the numbers and proportion of young people in college, the expansion of university systems, and the consolidation of the disciplinary structure of modern scholarship. American social science gained in prestige and resources, as government funders joined private foundations in research grants and large-scale survey-research centers blossomed at Columbia, Chicago, and Michigan. This heyday in advanced social science research spawned the conviction, fairly prevalent among liberal scholars, that a new Enlightenment had arrived, promising to deliver sound knowledge of social affairs in value-neutral terms (Brick, 2000: pp. 24–33).

These conditions set the stage for a flourishing debate over the end of ideology, focused on the value of consensus or dissent in social and political life, the epistemological status of the social sciences as they become embroiled in contentious political affairs, and the degree to which academic affairs could or should be shielded from political controversy. A leader of the left-wing Students for a Democratic Society, Alan Haber, wrote in 1962 that ideology need not be doctrinaire, millenarian, or violent: rather, ideology comprised a set of moral values that sustained political criticism, a definition of the 'good society,' and a strategic plan of action dedicated to realize it (Waxman, 1969: pp. 182–205). The young Yale political scientist Joseph LaPalombara defined ideology as "a philosophy of history, a view of man's present place in it, some estimate of probable lines of future development, and a set of prescriptions regarding how to hasten, retard, and/or modify that developmental direction" (Waxman, 1969: p. 320). Defined in these terms, ideology's 'end' appeared not at all to be a benign outcome. In fact, C. Wright Mills argued, the end-of-ideology doctrine "stands for the refusal to work out an explicit political philosophy"; it amounted to an "intellectual celebration of apathy" based upon "a disbelief in the shaping by men of their own futures." Moreover, 'end-of-ideology' notions forgot that every social theory presupposed an 'ideological' or evaluative stance toward the given realities of society and the uses of power within it. By pretending, allegedly, that intellectual work could be free of political commitment, the end-of-ideology thesis simply masked its proponents' embrace of 'society as it is, a going concern' – and bowed to the narrow-minded empiricism that prevented American social science from broaching big questions about the nature of social order and pressing demands for social change (Mills, 1963: pp. 247–259).

Almost none of Bell's critics, however, directly challenged his central argument that socialism – as the concerted program of a dedicated political party advocating revolutionary social transformation – had lost relevance to the problems of Western industrial society. In fact, in this respect, there was a great deal of agreement on such central 'end-of-ideology' arguments between its main exponents and their most vigorous critics. The sociologists Stephen Rousseas and James Farganis, who like Mills reproached Bell for his alleged 'apotheosis of a noncommitted scientism,' claimed only to advocate 'long-range planning on a governmental level' that would "make the capitalist system viable in a power world [i.e., a world marked by systems of highly organized, centralized power that made old market ideology of decentralized competition obsolete]." In these terms, the end-of-ideology debate was not much of a debate at all, but a combination of misunderstandings, claims to marginal differentiation, or a contest between distinct *styles* of responding to conditions of welfare-state capitalism, which looked very much the same to most of the contenders. Much of the debate actually steered away from substantive argument over the structural character of the contemporary social organization of political economy and led to chest-thumping and self-regarding recriminations over the status of what a later generation would call 'public intellectuals.' Writing in the social-democratic journal *Dissent*, Dennis Wrong agreed that the threat of totalitarianism and successes of the welfare state had reduced the salience of independent socialist movements; yet, the end of ideology made a cult of moderation and accepted a consensus providing little room for debate. In an age marked by the end of ideology, he warned, intellectuals fail "to perform their roles as unattached critics and visionaries" (Mills, 1959; Waxman, 1969: pp. 116–125, 206–207, 221–222, 338).

Bell indeed abjured the role of 'visionary,' though he retained a deep interest, stemming from his Marxist origins, in 'forecasting' changes in social structure of an 'epochal' character – hence his work, beginning at that time, on 'postindustrial society.' He nonetheless took umbrage at other attacks, claiming his critics knew the title but not the contents of *The End of Ideology*. In fact, he evinced a strong interest in the radical critique of bureaucratic order. In one of the classic essays in the book, Bell marked the 'cult of efficiency' in a mass-consumption economy, embraced not only by corporate management but by the workers who suffered the hierarchical regimentation of mass production, as a proper target for criticism. Combating this 'cult' in his essay, 'Work and Its Discontents,' Bell mocked the 'scientific' approach of industrial engineers to conflict resolution and called instead for 'new, humanistic' approaches to work that would break down centralized controls and attack the alienation or estrangement induced by the gulf between labor and meaningful activity. "For the unions to challenge the work process would require a radical challenge to society as a whole," Bell wrote, adding that 'the exploration of such a road is necessary.' And Bell needed no lessons about the value-laden character of social analysis. "'The idea that a scientist simply studies 'what is,' as John Dewey has argued, is a parochial conception of science.… As Dewey said forcefully on another occasion: 'Anything that obscures the fundamentally moral nature of the social problem is harmful'" (Bell, 2000b: pp. 391, 386–387, 249, 237). Nor, contrary to those who saw 1960s protest as disproof, did his idea of the end of ideology ever deny the persistence of political conflict. In fact, he asserted that the new conditions of a politicized economy would, if anything, stir sharp new controversies (American Academy of Arts and Sciences, 1967: p. 7).

Bell's analysis and evaluation of American or 'Western' society during the period of postwar reconstruction and the 'end of ideology' had always been ambivalent, signaled by the subtitle of his book, 'The Exhaustion of Political Ideas in the Fifties,' which not only lacked any celebratory ring but came close to sharing his critics' disheartened view of the status of acute political thinking. On the one hand, as his conclusion to *Marxian Socialism* and the later work on postindustrialism indicated, Bell considered most inherited doctrines of social science and political theory irrelevant to addressing the real problems posed by the new shape of things. On the other, he recognized the shortfall of contemporary political debate:

> The pacifist and Socialist elements have been unable to make the peace issue salient. The radicals have been unable to develop a comprehensive critique of the social disparities in American life—the urban mess, the patchwork educational system, the lack of amenities in our culture. Among the liberals, only the exhaustion of the "received ideas," such as they were, of the New Deal remains. It

is a token of the emptiness of contemporary intellectual debate that from the viewpoint of the radical right, the Americans for Democratic Action constitutes the 'extreme left' of the American political spectrum.

He *bemoaned* the fact that "a viable left [does not] exist in the United States today" (Bell, 2002: p. 41).

Still, given his staunch anticommunism, his feud with C. Wright Mills and his contemptuous view of Mills's 'Power Elite' thesis, and his highly ambivalent, uncertain view of American social structure, Bell's writing featured few strongly worded sallies against the status quo. In line with his view that aspirations for social change and thorough-going reform – the principle of 'utopia' he still considered valid – must offer an 'empirical' path forward, specifying "*where* one wants to go, *how* to get there, the cost of the enterprise, and some realization of, and justification for the determination of *who* is to pay," Bell cofounded the journal, *The Public Interest* in 1965 to offer social–scientific knowledge and judgment on behalf of liberal social policy. While turning a skeptical eye toward elements of Lyndon Johnson's Great Society programs, such as the principle of 'maximum feasible participation' by community members in antipoverty efforts – and an opposition, generally, to the 'populist' spirit of the times – the *Public Interest* also provided the venue for liberal economists who developed the basic-income proposals that George McGovern advanced in his failed 1972 presidential campaign.

For much of the 1950s and 1960s, Bell and his associates devoted attention to the threat of 'the radical right,' which had gained prominence in US political life in the guise of Joseph McCarthy's alarmist conspiracy mongering and later, after McCarthy's censure, the John Birch Society, militia groups such as the Minutemen, and the Goldwater tide within the Republican Party. In a collection of essays first published in 1955 and then reissued as The Radical Right in 1962, Bell collaborated with historian Richard Hofstadter (as well as sociologists Talcott Parsons and Seymour M. Lipset) to venture a new analysis of political movements based on 'status anxiety' or 'status politics.' That is to say, right-wing surges like McCarthyism stemmed less from 'interests' based in one's social class than from anxieties over the prestige or moral standards one's group held, ways of life perceived to be threatened by social change or even, perhaps, dislocated by the experience of economic growth and prosperity. For Bell, this approach was wedded to his critique of orthodox Marxian views on the primacy of 'class' (and his view that this was a 'crude lens' for social and political analysis); for Hofstadter, it was closely related to his critique of Populism and Progressivism for seeking to hold on to outmoded views that placed simple farmers or the moral middle class at the heart of the Republic. Critics argued, variously, that the 'status' analysis neglected the 'real' economic grievances of middling farmers, unjustly suggested a link between right-wing McCarthyism and the old reform movements, missed the evidence of conventional business- or upper-middle-class conservatism behind McCarthy's campaigns, and mistakenly reduced the Right to a psychic pathology or a 'backward' perspective resisting, but bound to be outmoded by, ongoing 'progress.' Thus, according to its critics, the 'status' analysis missed the potency and future success of the conservative movement. Many of these criticisms were ill-informed or misguided, and Bell would later claim that *The Radical Right* effectively introduced the idea of 'cultural politics' that would prove in fact a key element of conservatism in the last quarter of the twentieth century (Bell, 2002).

Postindustrial Society and Cultural Contradictions

The main drift of Bell's work, however, led toward his portrait of postindustrial society. He did not invent the term, but as he worked the theme throughout the 1960s, he became the writer most closely associated with it. He began plying the theme around 1959–62, and a well-developed version of it debuted in a two-part article published in *The Public Interest* in 1967, prior to a major draft in 1969–70 that led to *The Coming of Post-Industrial Society* in 1973. Several traits marked the advent of this new order, including the rising weight of the 'tertiary' or service sector in the economy, but Bell more importantly defined postindustrial society as "one in which the intellectual is predominant." By that he meant not that intellectuals became a new ruling class but that the expanding social functions of science, the development of computer-based techniques of modeling and simulation, and growth in both public and private funding of research and development all contributed to making intellectual institutions (most notably the university) as socially 'central' in contemporary society as the business corporation had been in recent times. Bell always balanced skepticism about grand claims of postindustrial abundance through automation with an emphasis on new, emergent social principles that could transform human relations. The preeminence of 'theoretical knowledge' (basic, rather than applied, science) demanded an 'orientation toward the future' that was the watchword of postindustrialism. Only such forethought could provide long-term guidance to the generation of knowledge as a social and economic resource. A society organized to anticipate long-range needs was perforce focused on central, national institutions; at the moment he wrote, recent civil rights laws lent some plausibility to his claim that American life had entered a new period in which "the conscious direction of social change [is undertaken] by the federal government" (Bell, 1999, 1966: pp. 36, 70–88).

In a way, Bell's view of postindustrial society forecast a future in which the evolutionary development of the welfare state enabled a democratic polity to shoulder tasks of social planning. Here, his skeptical and progressive inclinations worked together, for only the assumption of persistent scarcity made public planning an imperative, resting on the need to choose between alternative allocations of resources that (like knowledge itself) were essentially and profoundly social. If, in Bell's mind, postindustrial society could not be considered 'posteconomic' in the sense of having escaped scarcity, it nonetheless pressed beyond the logic of markets: he argued that postindustrial trends elevated a new 'sociologizing' mode of decision-making over an 'economizing' mode. The first comprehended integral social processes involving nonprivate resources and goods such as education and environmental quality, while the second demanded only the efficient

allocation of discrete inputs to given production processes. Bell consistently resisted the inference some readers drew that his postindustrial society could no longer be understood as 'capitalist.' Still, his forecast suggested a society that looked significantly different from most conventional definitions of capitalism: the United States, he wrote, was "moving away from a society based on a private-enterprise market system toward one in which the most important economic decisions will be made at the political level"; "production and business decisions will be subordinated to, or will derive from, other forces in society" (Bell, 1999: pp. 344, 481).

As always, a certain degree of self-conscious ambiguity prevailed in Bell's analysis. The trait other writers put at the heart of postindustrial visions – the apparent rise of consumer culture supplanting 'productivist' values – as well as the persistence of capitalism in contemporary society provided the key themes of Bell's next book, *The Cultural Contradictions of Capitalism*. It had been drafted in 1969–70 as part of the same manuscript that yielded his *Post-Industrial Society*; the timing was telling. His part in a faculty committee trying to negotiate a resolution to the Columbia student protests of 1968 had deepened his distaste for the New Left (and, on the other side, for hard-liners who summoned club-wielding police to roust the radicals from their building occupations); he left Columbia to assume an endowed chair at Harvard University the next year. The kind of analysis he had applied to the Radical Right now focused on the New Left. According to Bell, 1960s left-wing radicalism bore the curse of 'mass politics,' manifesting a simplistic 'populism' – that is, a 'leveling' disposition – that challenged elites and repudiated any kind of legitimate authority. He also considered the 1960s 'counterculture' to be quite dated, a repeat of the 'modernist' rejection of social constraint and moral standards, now turned into a mass attitude. If his complaint over mass hedonism (signaled, he often asserted, by the flaunting of sexuality) struck some ears as prudery, his stance actually rested on a concern closely wedded to what Emile Durkheim originally meant by 'anomie' – not so much egoism as such but rather a kind of disorientation, conceivably stirred by prosperity itself, that so unhinged social norms as to leave impulses entirely unregulated.

Bell's *Cultural Contradictions* saw in these recent trends an antinomian dynamic of self-gratification that undermined the communal ethos needed for society to take advantage of the new modes of social planning made available by postindustrial trends. And that dynamic arose from the individualistic, consumerist passions spawned by capitalism, which thus appeared as the force spoiling the prospects of social-democratic advance. While his book title indicated the ways that new mass-culture impulses contradicted the moral foundations (in a Protestant work ethic) on which capitalism originally legitimated itself, Bell had little interest in defending capitalism as such. In terms that evoked, instead, his old left-wing origins, he argued that as the consumer market sundered its ties to the moral imperatives of work, capitalism had lost its 'transcendent ethic.' Bell claimed "the social order lacks either a culture that is a symbolic expression of any vitality or a moral impulse that is a motivational or binding force." Capitalism could offer no way forward; it was 'ideologically impotent.' What the emerging postindustrial society needed was what Bell called a 'public household' – 'an effort, in the realm of the polity, to find a social cement for the society,' or better put, the value-laden principles of decision that put a 'pilot' in the seat of government, 'the cockpit' of the postindustrial order in his view, to steer socioeconomic allocations as the market lost primacy and precedence (Bell, 1996b: pp. 84, 278).

In effect, Bell in the 1970s turned right in his recoil from the New Left and simultaneously turned left in his revitalized skepticism of capitalist norms. Surely, he did not share the Marxist or neo-Marxist assumptions of writers such as James O'Connor and Jürgen Habermas. He denied that there was a general systemic dynamic that made a coming social crisis inevitable. Having earlier dismissed his youthful confidence that socialism was destined to replace capitalism, Bell was prepared to address the crosscurrents of the 1970s as a manifestation of what he now called 'the disjunction of realms,' the argument that societies did not hold together according to a central governing logic but incorporated several different axes of development. In the current case, these axes were a social realm governed by postindustrial trends, a political realm determined by liberal principles of individual rights and representative government, and a cultural realm dominated by modernist or postmodernist mass consumer desire (Bell, 1996b: pp. 3–30).

Cultural Contradictions was one of the earliest American works to examine postmodernism – the peculiar amalgam of styles and attitudes, which fused the modernist avant-garde with mass culture while spurning elements of modernity associated with the 'rational cosmology' of the Enlightenment. Among the features of this rebellion Bell identified an 'eclipse of distance' manifested not only in the avant-garde idea of fusing life and art (evident, among other things, in the way 'happenings' and other action-oriented art forms sought to erase the gap between the work as such and the spectator) but also in the breaking of boundaries between public and private life and a general loss of moral reserve. Boundaries were essential, he believed: in writings on religion, he rejected the old view of modernity fostering secularization – he highlighted the resurgence of religious identity and motivations in his essays from the 1970s to the 1990s – but argued that the distinct phenomenon of 'profanation' indeed characterized popular culture that, in denying 'distance,' disregarded the realm of 'the sacred' (Bell, 1996b, 1980: pp. 99–119, 324–354).

Much of Bell's sensibility stemmed from his participation during the late 1940s in a kind of religious revival among Jewish intellectuals, who shared a new interest in theology, respect for religious experience, and the sentiment of belonging to a people having a transhistorical identity. Without claiming a personal conviction of faith, Bell came to voice a deep appreciation for the value of tradition, a sense of depending on larger things, and the need to accept constraint on impulse and personal gratification. This disposition carried over to social affairs as he insisted on the role that authority – that is, respect due to professional, political, and cultural elites – played in granting society continuity and stability, a precious achievement, he believed, in a world of many atrocities. Hence Bell's call in the 1970s and 1980s for the 'restoration of authority' in American life, combined with his bitter

denunciations of 1960s radicals and their legacy, constituted a genuinely conservative element of his thought (Bell, 1985).

Still, it was a mistake to associate Bell, as many critics did, with neoconservatism (Steinfels, 1979). He refused to follow the rightward current that led some postwar liberals, like his friend Irving Kristol, to join first the Nixon campaign of 1972 and later the Reagan coalition of the 1980s. It was Kristol's endorsement of Nixon (while Bell backed McGovern) that highlighted the political gap between them and led Bell to resign from the editorial board of the journal he cofounded, *The Public Interest*. Reaganism, for Bell, connoted an 'ideologizing' of capitalism, an outburst of crabbed religious moralism that threatened rights of privacy, and a desecration of the public household. Against claims that he joined Kristol's promotion of neoconservatism, Bell ventured his famous self-definition as "a socialist in economics, a liberal in politics and a conservative in culture." The formula mirrored his theoretical view on 'the disjunction of realms' and accurately summed up his dispositions. The 1980s found him writing in *Dissent*, and in its pages – and at a 1990 Mexico City conference drawing many of his old CCF colleagues together to reflect on the fall of the Berlin Wall – he wrote that "socialism, in the classic sense, has not failed, for it was never tried. It remains, like all ethical creeds, an ideal, a measure of potentiality and possibility, against reality. That has always been the function of utopia. The mistake was to assume that utopia could come down from the mountain and assume human form" (Bell, 1990: p. 188). He insisted, nonetheless, that such an ethical creed, devoted to 'equity, justice, and dignity' as against 'egoism' remained his own benchmark. In essays of the same period, Bell continued to probe the social and political implications of recent technological and economic innovations, particularly the 'problem of scale' that rendered the modern nation-state unfit either to manage a new economy of global range or to foster local participatory institutions that could give people a stake in civil society, understood in his liberal view as "tolerant and pluralist" (Bell, 1990: p. 188).

While the fall of the Soviet Union led observers to claim that Bell's *End of Ideology* had been vindicated, his perspective was falsely assimilated to the like-sounding title of Francis Fukuyama's *The End of History and the Last Man* (1991). According to Fukuyama, the end of the Cold War marked the 'end' of fundamental conflict between opposed visions of the good society, and it signaled the establishment of a broad consensus that only liberal democracy could truly fulfill the aspirations implicit in human reason and desire for prosperity and the recognition of personhood and fundamental rights. Ostensibly like the end-of-ideology writers in the 1950s, who saw Western society passing a threshold in which old 'ideological' illusions 'are dissolving and collapsing like a dream picture' (as Fukuyama quoted Hegel), Fukuyama celebrated a now world-ranging consensus on liberal values. Seemingly like end-of-ideology writers, he stated that "in most advanced democracies the big issues concerning governance of the community have been settled, reflected in the steady narrowing of the already narrow policy differences between political parties in the United States and elsewhere" (Fukuyama, 1992: p. 317). Yet in fact, Fukuyama's perspective was light-years apart from the end-of-ideology thesis, not only because Fukuyama's supposed final resolution of fundamental social and political disputes entailed an unambiguous settlement on the virtue and efficacy of free-market capitalism (never avowed by the end-of-ideology social democrats), but more importantly because Fukuyama built his argument by resurrecting Hegel's Universal History, whereby the 'cunning of reason' finally led to the end of all basic questions and struggles of social and political existence. In other words, Fukuyama's 'History,' having ended, evoked precisely the overarching schemes and systematic philosophy that the end of ideology had considered the curse and cause of the worst modern nightmares.

It was due to the distance between his own views and those like Fukuyama's that the new forward Bell wrote for the year 2000 edition of *The End of Ideology* was entitled, 'The Resumption of History in the New Century,' and why he worked over a manuscript entitled 'The Rebirth of Utopia' in his last decade, telling a young sociologist in 2004 that the forward-looking virtues of 'utopian' thought must still be valued and distinguished from the 'messianic' fervor for a brave new world coming in our time (what he always meant by 'ideology') (Bell, 2000b: pp. xi–xxviii; Beilharz, 2006). As always, however, the campaign against 'messianism' drew more of his attention than a focused discussion of viable 'utopias' (apart from his affirmation of a socialist ethic); also, while he assailed the Reagan ascendancy for granting full legitimacy to the Radical Right and its 'distinct tones of divisiveness and dark incitements of conspiracy,' he welcomed any sign of social 'stability' and civility at the political center (which he mistakenly perceived at the beginning of the George W. Bush years) (Bell, 2002: pp. 478–479). As a consequence, while he was more or less a 'man of the left' all his life, his death brought competing interpretations ranging from 'Daniel Bell, American Menshevik' to 'Daniel Bell, Conservative' (Beilharz, 2013; Murphy, 2013). He was in any case the American sociologist best known around the world, whose works were more widely read than those of the grand theorist, Talcott Parsons, who dominated the discipline when Bell entered it in the 1950s. By all accounts of those who knew him well, he would have welcomed continuing argument over the social, political, and moral implications of his ideas.

Abstract

Robert N. Bellah (1927–2013) was an American sociologist, public intellectual, and educator. A student of Talcott Parsons, he became known in the 1950s as a Japanologist and a theorist in the sociology of religion. During the 1970s, he started the 'American civil religion' debate and contributed to the interpretive/hermeneutical turn in the social sciences. In the 1980s, he was one of the coauthors of one of the most successful books in the history of sociology, *Habits of the Heart*. Toward the end of his life he published his *magnum opus*, *Religion in Human Evolution*.

Becoming a Social Scientist

Robert Neelly Bellah was born in Altus, Oklahoma, on 23 February 1927, to a Presbyterian family of Scotch-Irish and English descent. He grew up in West Los Angeles and attended Los Angeles High School, where he edited the school daily newspaper, *Blue and White*, and was involved in student government. A high achiever, Bellah formed a wide circle of friends, including Jewish students, with whom he shared an interest in liberal politics, classical music, and literature. One of them, Melanie Hyman, would become his wife in 1949. In 1945, Bellah entered Harvard College, where he received a BA in social anthropology in 1950 from the Department of Social Relations. His honors thesis, *Apache Kinship Systems*, won the Phi Beta Kappa Prize and was published by Harvard University Press in 1952.

Established in the summer of 1946, the Department of Social Relations was the institutional base of an ambitious interdisciplinary project envisioned by Talcott Parsons, Clyde Kluckhohn, Gordon Allport, and Henry A. Murray. The Department aimed at integrating the 'basic social sciences' (sociology, cultural anthropology, clinical and social psychology) as the foundations upon which any scientific study of human behavior should be built (Gilman, 2003). Parsons and his colleagues created an ambitious graduate studies program in which different disciplinary streams of research would interact in intense mutual interchanges. While the Department never reached the scientific and professional integration Parsons had hoped for, its results were remarkable: during its first 10 years it recruited George Homans, Samuel Stouffer, Jerome Bruner, David Riesman, and Erik Erikson as faculty members, and granted doctoral degrees to scholars like Harold Garfinkel, Clifford Geertz, and Neil Smelser.

In 1951 Bellah began a joint doctoral program in Sociology and Far Eastern Languages and started working on a dissertation inspired by Max Weber's sociology of religion. Applying Weber's thesis linking the Protestant ethic and the spirit of capitalism to Tokugawa Japan (1600–1868), he aimed at describing the emergence of religious movements analogous to the Protestant sects as carriers of the rational and methodical ethic needed for the takeoff of modernization. With Parsons and John Pelzel as his advisors, Bellah worked on the dissertation until the summer of 1954, when he experienced the troubles of McCarthyism on campus.

As an undergraduate inspired by the ideals of social democracy, Bellah had been a member of the John Reed Club, a Marxist organization at Harvard College, and identified as a Communist. Despite his personal disillusionment with Stalinism and his subsequent break with the party in 1950, in the summer of 1954 Bellah was asked by the dean of the Faculty of Arts and Sciences, McGeorge Bundy, to cooperate with the FBI, but he refused to denounce his old comrades. Some months later, when Parsons proposed Bellah for an instructorship in the Department of Social Relations, the interrogation began again. While Parsons and other colleagues backed him, in 1955 Bellah decided to leave Harvard and accepted a 2-year fellowship at the Institute of Islamic Studies established by Wilfred Cantwell Smith at McGill University in Montreal, Canada.

Bellah at Harvard

Declining offers from McGill and Columbia University, Bellah went back to Harvard on a fellowship at the Center of Middle Eastern Studies which was converted into a 4-year appointment to the Faculty of Arts and Sciences and the Harvard Divinity School in 1958. His immediate circles abounded with eminent figures. Paul Tillich, Krister Stendhal, and, after 1964, Cantwell Smith were among his colleagues at the Divinity School, while the Department of Social Relations was becoming America's most influential sociology department. In area studies, Bellah was mentored by Edwin Reischauer, H.A.R. Gibb, Serge Elisséeff, and John Fairbank. He regularly taught classes on Islam, China, Japan, and courses and seminars on the history and sociology of religion, Weber, and Émile Durkheim with Talcott Parsons. Bellah spent a year (1960–61) in Japan and was a fellow at the Center for Advanced Studies in the Behavioral Sciences at Stanford in 1964–65. He was appointed associate professor in 1961 and full professor in 1966.

During his first decade as a scholar, Bellah was an integral member of two of the most influential networks of the postwar social sciences, those promoting structural functionalism and modernization theory. Led by Parsons and Robert K. Merton, structural functionalism was characterized by a naturalistic understanding of the social sciences; an analytical conception of sociological theory; an interest in European theorists; and

the search for functional explanations of social phenomena in terms of normative structures and moral schemata. Influenced by America's Cold War response to Marxist (and thus Sovietic) depictions of the rise of industrialism, modernization theory was an evolutionary theory of societal change loosely founded on a Parsonian systemic framework. In particular, the work of modernization theorists was informed by a sharp distinction between traditional and modern societies; a systemic depiction of societies as differentiated but quasi-coherent wholes; an explanation of social change as a unilinear sequence of evolutionary stages; an allegedly technocratic and postideological understanding of public life; and an identification of the United States as the apex of the modernization process.

A participant in the institutions where these networks intersected – the Department of Social Relations, the Committee for the Study of the New Nations at Chicago, and the MIT Center for International Studies – Bellah developed structural-functionalism and modernization theory as an analytically informed macrosociology focused on the problem of meaning in modern and modernizing societies. In typical Social Relations fashion, he carefully combined the study of symbolic systems, psychological motives, and social structures, while his deep engagement with Weber and Durkheim extended Parsonian analysis by incorporating the historical side of their writings. In *Religious Aspects of Modernization in Turkey and Japan*, Bellah (1958) hypothesized that the differentiation between religion and political ideology, a property of modern societies, could only be brought about by movements able to challenge the religious foundations of 'old,' undifferentiated traditional societies. In *Durkheim and History*, he vindicated the French sociologist's (and, by extension, structural functionalism's) interest and ability to study social change (Bellah, 1959).

Bellah's second book, *Tokugawa Religion: The Values of Pre-Industrial Japan*, was published in 1957. It laid on a synthesis of structural-functionalism, modernization theory, and his more culturalist orientation. Bellah explained Japan's successful modernization pointing to the paramount importance given to political loyalties and relationships within the country's 'central value system.' Using a complex theoretical framework built on Weberian concepts and Parsons' pattern variables and four-function (AGIL) paradigm, Bellah (1957) compared Japan's 'political values' to America's 'economic values' and China's 'integrative values,' and described their different paths to modernization. As the capital needed to catch up with Western capitalist countries was too great to be supplied by the economy alone, the particular orientation of its value system was instrumental in giving Japan an edge over its main Eastern competitor: during the Tokugawa period, the government had succeeded in mobilizing political loyalties toward industrialization and in orienting the population toward national development. Religious commitments made sure that political values and allegiances were 'meaningful in an ultimate sense' and gave a metaphysical justification to the Restoration of the Emperor, itself a major disruption of existing social and cultural structures. Following Weber's lead, Bellah focused on a spiritual movement, Shingaku, as a proxy for the inner-worldly asceticism that the German sociologist had deemed crucial for the emergence of the spirit of capitalism. The book closed on a critique of materialist versions of modernization theory and pleaded for a multidimensional analysis of industrialization that would not consider the United States the sole example of successful modernization.

Reviewers praised *Tokugawa Religion* for its use of the Parsonian framework to shed light on some of the most important questions of Japanese economic and political history. The book was reviewed by Japan's foremost political scientist and philosopher, Maruyama Masao, who criticized Bellah's interpretation of the role of Shingaku and the Restoration of the Emperor, but also compared him to Ruth Benedict. In his subsequent work, Bellah abandoned the search for Protestant ethic analogies in Asia, focusing instead on those twentieth-century intellectuals, such as Ienaga Saburo and Watsuji Tetsuro, who had tried to make sense of Japanese modernization (see Bellah, 2003). In the early 1960s, Bellah's involvement in the Conference for Modern Japan marked his entry into the pantheon of American Japanologists.

In his more theoretical work, Bellah sought to create a multidimensional analytical framework based on Parsons' AGIL model. In *The Systematic Study of Religion*, an unpublished paper widely circulated in the mid-1950s, he assigned the label 'religion' to the most abstract subsystem of the cultural system, its main functions being the maintenance of meaning complexes and the management of psychological tensions. As Parsons himself had done in a number of essays and articles, Bellah ruled out the very possibility of a fully secularized society: from an analytical point of view, no society could do without 'religion,' so that if traditional religions could not fulfill the functions of pattern maintenance and tension management, other symbols, actions, and institutions would emerge and replace them. This position informed Bellah's major theoretical piece of the early 1960s, *Religious Evolution*. Bellah had begun his reformulation of one of classical sociology's main themes while in Montreal, and worked out his ideas in a seminar he led with Parsons and Shmuel Einsenstadt at Harvard – the three men each published an essay on evolution in a special issue of the *American Sociological Review* in 1964.

Starting from a Tillichian definition of religion as "a set of symbolic forms and acts that relate man to the ultimate conditions of his existence," Bellah (1970a) described the evolution of religious symbolism within the context of growing differentiation, rationalization, and emancipation of humankind from its material, social, and metaphysical environments. Religious evolution went through five stages: (1) *primitive religion*, where mythic symbol systems combine with ritual participation, and religious organizations correspond with whole societies; (2) *archaic religion*, characterized by complex social differentiation and the development of differentiated gods, who are nonetheless ancestors or kin of the high chiefs or noble classes who rule; (3) *historic religion*, in which there is a radical break between two different realms, mundane and transcendent, and religious action becomes oriented to gain salvation from worldly evils; (4) *early modern religion*, which comprises only a single case, the Protestant Reformation, based on the direct relationship between the individual and transcendent reality, a devaluation of ritual, and the diffusion of 'religion' through everyday life; (5) *modern religion*, a post-Protestant phase where monist and dualist representations give way to an 'infinitely multiplex' world and life is an 'infinite

possibility thing.' The search for ultimate meaning turns into an experimental, ever-changing activity, while religious organizations become deeply individualized – up to the point that each individual becomes a 'sect himself.'

The Civil Religion Debate

Bellah's ambivalent conclusions to 'Religious Evolution' – "No doubt the possibilities for pathological distortion in the modern situation are enormous (…) Yet the very situation that has been characterized as one of the collapse of meaning and the failure of moral standards can also, and I would argue more fruitfully, be viewed as one offering unprecedented opportunities for creative innovation in every sphere of human action" (Bellah 1970a) – were an anticipation of a major change in his intellectual and personal standing as a scholar. As the 1960s came to an end, Bellah was slowly distancing himself from the ideas and the networks that had made him a well-known Japanologist and theorist of religion. First, he was discarding functionalism in favor of an original synthesis between historical sociology and a deep hermeneutic of the symbolic dimension of social and cultural phenomena. Second, in his language and argumentation Bellah was creating an evocative and metaphorical vocabulary which bore no resemblance to Parsons' esoteric jargon. Third, from an organizational point of view, while his mentor was the foremost proponent of a differentiated sociology, Bellah assumed a cross-disciplinary posture and started to reflect on the artificiality, and ultimately the unsuitability, of scholarly boundaries. Last but not least, he abandoned Parsons' detached, professional stance and became increasingly involved from a personal point of view. Bellah's intellectual shift was also accompanied by a major existential change. After declining offers from the University of Michigan, UCLA, Columbia University, and the University of Chicago, he finally left Harvard in the spring of 1967 to become Ford Professor of Sociology and Comparative Studies and chairman of the Center for Japanese and Korean Studies at the University of California, Berkeley, and an adjunct professor at the Berkeley Graduate Theological Union.

Civil Religion in America was probably the most significant instance of this profound change. In October 1965, Bellah participated in a conference on 'Religion in American Culture' at the American Academy of Arts and Sciences. Although not a specialist, Bellah had written occasionally on American religion in the 1950s and 1960s. His paper for the AAAS, *Heritage and Choice in American Religion*, received notice for its use of the Rousseauian concept of 'civil religion.' The final version of the paper, titled *Civil Religion in America*, was published on the winter 1967 issue of *Daedalus*. Bellah's main point was spelled out unambiguously in its very first lines: "There actually exists alongside of and rather clearly differentiated from the churches an elaborate and well-institutionalized civil religion in America" (Bellah, 1970a). According to Bellah, a set of shared symbols, beliefs, and rituals rooted in the language and imagery of the Old Testament, but also 'genuinely American and genuinely new,' had historically substituted for the lack of an established religion. This American civil religion had been shaped by two crucial moments of national history, the Revolution and the Civil War, which had introduced 'a new theme of death, sacrifice, and rebirth' symbolized by Abraham Lincoln, the 'American Jesus.' As the late 1960s emerged as a 'third time of trial,' the civil religious tradition could serve as an inspiration for the United States to contribute to the creation of a world civil religion. Just like any tradition, Bellah concluded, the American civil religion could never transcend moral ambiguity, but it might be a guide for righteous action when correctly understood and enacted.

Although the theme was not new, Bellah's conceptualization of the American civil religion immediately caught on and generated a wide and raucous debate which involved sociologists, historians, theologians, and political scientists on both sides of the Atlantic. Bellah decided to participate in the discussion out of his political concerns after the escalation of the Vietnam War and his disappointment in the scholarly status of coeval sociology of religion. Between 1968 and 1980, Bellah participated in countless conferences, symposia, and public meetings with academic and nonacademic audiences where critics discussed the value and the uses of the concept. As a newcomer to American studies, he had to immerse himself in a crash course in the history of the United States and he profoundly changed his own perspective on the civil religion in the process. A first reformulation of his ideas was presented in the fall of 1971 in the Frank L. Weil Memorial Lectures in Cincinnati, where he said that the original American civil religion had always been unable, by itself, to raise the moral standards of the nation, and only exceptional presidents like Jefferson or Lincoln had been able to give it the force and appeal it needed to function as the critical conscience of the American people. Moreover, the civil religion had always been accompanied by the public-spirited interventions of theologians and pastors, so that it had been 'the churches who spoke with the combined voice of the believers and citizens.' In subsequent essays, Bellah considered the civil religion as one of two competing cultures – biblical-republican and liberal-individualistic – which had struggled for the soul of the American people ever since the founding of the early Bay colonies.

These ideas found a comprehensive formulation in Bellah's (1975) book, *The Broken Covenant: American Civil Religion in Time of Trial*, which expanded the Weil Lectures in a critical appreciation of the symbolic and mythical life of the United States from John Winthrop's speech on the Arbella to the Vietnam War. In the conclusion, Bellah (1975) famously wrote not only that "today the American civil religion is an empty and broken shell," but also that it had been, "from the beginning an external covenant," that is, a *modus vivendi* and not a shared *conscience collective*. Bellah feared that the utilitarian-individualistic tradition would finally impose itself on the more solidaristic, biblical-republican one, thus undermining the very bases of American society and transforming the latter into a bureaucratic authoritarian nightmare. The book was widely acclaimed and won the Sorokin Award of the American Sociological Association for 1976. At the same time, it was heavily criticized by Parsons before and after publication. Bellah's old mentor was disappointed at both the book's grim diagnosis of the moral malaise of American society and its passionate, almost prophetic tone. In *Law as an Intellectual*

Stepchild, Parsons (1977) portrayed *The Broken Covenant* as excessively Manichean and called Bellah 'a moral absolutist.'

Interpretive Social Science and the 'Bellah Affair'

As the American civil religion debate was turning him into a star of American studies, Bellah managed to publish a host of methodological essays that challenged the received wisdom of the sociology of religion in mid-century America. Embarrassed by being too close to theology and not 'scientific' enough, the sociology of religion had enthusiastically embraced the naturalistic positivism of the 1950s and set out to come of age as a modest, unpretentious, and 'objective' subfield of social science. In *Transcendence in Contemporary Piety* Bellah abandoned his previous functionalism for the concept of *ultimate symbols* – defined as those symbols which represent the unity of all beings and that overcome ordinary dichotomies bringing together 'the coherence of the whole experience.' In a short autobiographical piece, aptly titled *Confessions of a Former Establishment Fundamentalist*, he repudiated the naturalistic logic of the postwar social sciences – and with it his own Parsonian upbringing – in favor of a hermeneutical approach to the study of religion (Bellah, 1970a, 1970b).

Bellah publicly discussed his new stance at a joint session of the Society for the Scientific Study of Religion and the American Academy of Religion held at the Sanders Theater, Harvard University, on 25 October 1969. There he attacked both the reductionist rationalism of Enlightenment social science and the unreflective, first-order naïveté of traditional religious education. Both perspectives had to be abandoned in favor of a new framework, 'symbolic realism,' which would recognize the *sui generis* reality of religious symbols, and would blur the boundary lines between social science, the humanities, and theology. According to Bellah, religious symbols were attempts to grasp "the totality which [included] subject and object and [provided] the context in which life and action finally [had] meaning." As such, they could be interpreted and understood only if scholars would embrace a particular attitude, which he called, following Paul Ricoeur, a 'second naïveté,' according to which any interpretation of reality, even science and rational thought, should be treated as 'only an interpretation, and not reality itself.'

Bellah's first collection of essays, *Beyond Belief*, was published in 1970. It included all his major papers along with a dense introduction where he worked out the connection between his personal experiences and his professional work, and made a plea for the establishment of interdisciplinary departments of religion in all universities, whether public or private. Ideas about symbolic realism were further elaborated in Bellah's introduction to his edited collection of Durkheim's writings on morality and society, and, more radically, in his many interventions about the teaching of religion, where he called for a new integration between knowledge, commitment, and faith. While the perspective of symbolic realism was reworked in a host of essays and articles, it was Bellah's forceful phrase – 'to put it bluntly, religion is true' – that continued to echo most memorably in the minds of his interlocutors. This made him the most radical proponent of what came to be called 'interpretive social science,' a loose movement which included former Parsons students, and Bellah's personal friends, David Schneider and Clifford Geertz, along with Victor Turner, Peter Berger, and Thomas Luckmann.

A major episode for Bellah's scholarly career came in 1973, when he was invited to take part in creating a school of social science at the Institute for Advanced Study at Princeton. Geertz, who had been appointed as the Institute's first permanent member of the social sciences in 1970, invited Bellah to join him in 1972, but the nomination aroused strong opposition from the Institute's mathematicians and historians. The Institute's director, former Harvard economist Carl Kaysen, pushed forward the nomination, which was approved by the Board of Trustees, against the majority of the Institute's permanent members. A harsh public quarrel ensued when confidential evaluations of Bellah's work were forwarded to the national press, threatening his scholarly reputation. The so-called 'Bellah affair at Princeton' abruptly ended when his eldest daughter, Tammy, committed suicide. Bellah and his family decided to leave the Institute and go back to Berkeley. The project of creating a recognizable school of interpretive social science was put aside, to be revived only when Bellah led a National Endowment for the Humanities residential seminar on 'Tradition and Interpretation: The Sociology of Culture' at Berkeley in 1976 and other similar enterprises (Rabinow and Sullivan, 1979; Bellah et al., 1983).

Habits of the Heart and Public Sociology

In 1976 Bellah and Charles Glock concluded a 5-year research project on new and 'chosen' religions and published *The New Religious Consciousness* (Glock and Bellah, 1976). Although the book was a diverse collection of ethnographies of religious and expressive groups, only partially reflecting the principles of symbolic realism, it constituted a diversion from the American civil religion debate, which Bellah found too focused on conceptual quarrels. His disappointment was partly due to the fact that his change of mind, spelled out in *The Broken Covenant*, had been barely noticed by his critics, who continued to attack an overly integrative, Durkheimian version of the civil religion thesis to which he had never subscribed.

Bellah then started working on a study titled 'The Moral Basis of Social Commitment in America' with four younger colleagues: Richard Madsen, a sociologist specializing in China; William Sullivan, a moral philosopher who had participated in Bellah's NEH seminar; Ann Swidler, a sociologist interested in cultural theory; and Steven Tipton, author of *Getting Saved From the Sixties* and the initiator of the project. In the meantime, Bellah's stature as a public intellectual continued to grow, as his many interviews and passionate interventions on American politics and religion show. In July 1979, he was invited along with other intellectual and spiritual leaders to advise President Jimmy Carter a few days before his famous 'Crisis of Confidence' speech (Horowitz, 2005). One month later, he delivered an intense

commemoration of Talcott Parsons, who had died in May 1979, and claimed his heritage for interpretive social science (Bellah, 1980). From 1979 to 1985 Bellah also served as Chair of Berkeley's Department of Sociology.

The results of the collective research were published in 1985 as *Habits of the Heart*, a phrase taken from Alexis de Tocqueville's *Democracy in America* (Bellah et al., 1985). The book, written for the general public, aimed at starting a 'conversation' on what it meant 'to create or preserve a morally coherent life' and focused on Bellah's cultural *bête noire*, individualism. Starting from a conception of culture as a multivocal conversation about three 'ultimate goals' – success, freedom, and justice – *Habits* presented a complex picture of the American symbolic realm, one that put individuals and their dignity at the center of moral discourse, albeit in very different ways. Bellah et al. identified four main cultural vocabularies: the republican and the biblical traditions, centered on a solidaristic understanding of moral life, and two individualistic traditions, which they labeled as 'utilitarian' and 'expressive' individualism.

From a sociological point of view, *Habits of the Heart* focused on four main topics: intimate relationships, civic and political involvement, psychotherapy, and religion. It attempted to create a continuous dialogue between the cultural heritage of American political and social history and the data collected interviewing some 200 average, middle-class Americans. In most of the cases, the authors' 'active interviews' with their fellow citizens revealed that the hegemonic language of individualism, whether utilitarian or expressive, was unfit to either describe or to make sense of the social and cultural relations in which ordinary people lived their daily life. Despite its clear Durkheimian roots and its penchant for an ecumenical version of the biblical – republican tradition, *Habits* did not portray America as an atomized, Hobbesian *Gesellschaft*. Bellah and his coauthors saw modern society as a combination of multiple 'communities of memory' – that is, groups of people who share a common narrative of their past, which they use to make sense of their lives, and who engage in continuous exchanges with each other.

The book abounded with evocative catchwords, among which 'Sheilaism' probably became Bellah's most celebrated intervention in the sociology of religion. Taken from an interview with the fictionally named Sheila Larson, it indicated a kind of do-it-yourself spirituality rooted 'in the effort to transform external authority into internal meaning,' a purely individualized creed assembled using bits of existing traditions. In the book's methodological appendix, 'Social Science as Public Philosophy,' Bellah attacked the allegedly value-free attitude of social scientists and pleaded for a publicly responsible social science, aware of the impossibility of separating cognitive and moral reasoning and committed to engage the lay public in dialogue. In his critique of existing social science Bellah was definitively abandoning his postwar upbringing and was translating his early symbolic realism in a more accessible version.

Habits of the Heart was a huge success. It was reviewed in *The New York Times Book Review*, *Newsweek*, *The Los Angeles Times*, and *The Times Literary Supplement* and became one of the all-time best sellers by sociologists (Gans, 1997). As its authors had hoped, it spawned a vibrant discussion among scholarly and lay publics, and was the object of countless reviews, meetings, and symposia. In 1986, *Habits* was nominated for the Pulitzer Prize for General Non-fiction; one year later, the team started working on a sequel, *The Good Society*, which was published in 1991. The new book focused on institutions and the cultural meanings that underlie them: the market, the government, schools and universities, and 'the public church' (Bellah et al., 1991). A more sociological book than *Habits*, *The Good Society* ended with a plea for democracy as 'paying attention.' As the senior member of the team, Bellah enjoyed most of the recognition for the two books and became one of the most cited public intellectuals in America (Posner, 2003). Despite his aversion to the term, in the 1990s he was often labeled a 'communitarian' – in part due to the fact that he was an early signer of Amitai Etzioni's 'Responsive Communitarian Platform.'

Back to Religion and Evolution

In 1997 Bellah retired from the University of California, but continued his scholarly work, publishing widely on American politics and society, the legacy of the classics, and education. His many interventions as an outspoken critic of unethical versions of individualism and his well-known sermons as a member of the Episcopal Church rounded out his public persona. In 2000 he was awarded the United States National Humanities Medal 'for his efforts to illuminate the importance of community in American society.' In the epilogue to his *Festschrift*, Bellah hypothesized the emergence of a new, post-Protestant society, one in which the 'axial' rupture between transcendence and the mundane order was somehow supplanted by a new form of 'disembedded immanentism' which threatened to turn all human action into technical calculation. As many of the essays collected in his eponymous *The Robert Bellah Reader* show, he found the roots of this grim development in some unredeemable 'flaw in the Protestant code' (Madsen et al., 2002; Bellah and Tipton, 2006).

More importantly, after retirement Bellah resumed a research project he had left dormant for nearly 30 years: writing a book on religion and evolution. In the early 1960s he decided to devote his scholarly life to a grandiose project, a rewriting of Max Weber's comparative sociology of religion in the terms of a theory of societal evolution. The American civil religion debate and the huge popularity of *Habits of the Heart* had 'distracted' him from this line of research, although the fivefold typology he had first spelled out in 'Religious Evolution' continued to be the backbone of his lectures on the sociology of religion at Berkeley. Preceded by some preparatory essays and a conference on 'The Axial Age and its Consequences for Subsequent History and the Present,' held at the University of Erfurt, Germany, in 2008 – in which Charles Taylor, Jürgen Habermas, Shmuel Eisenstadt, Jan Assman, and David Martin, among others, participated (see Bellah and Joas, 2012) – *Religion in Human Evolution* was finally published in 2011 by Harvard University Press.

In order to reconstruct the interactions between religion, social order, and the world of everyday life 'from the

Paleolithic to the Axial Age,' Bellah (2011) combined a Durkheimian definition of religion, centered on the notion of the sacred, with a more phenomenological, meaning-centered one, derived from the work of Clifford Geertz. From a theoretical point of view, religion was considered as a particular symbolic and institutional sphere that combined with biological, psychological, social, and cultural structures to create emerging structures and 'capabilities.' Conceptually, the most important advance with respect to Bellah's previous work was the combination of Jerome Bruner's four levels of representation with the four kinds of culture singled out by the evolutionary psychologist Merlin Donald: unitive symbols/episodic culture; enactive representation/mimetic culture; symbolic representation/mythical culture; and conceptual representation/theoretic culture. Each of these categories was considered as an autonomous evolutionary stage, emergent from previous ones and able to react on them. In fact, according to Bellah, 'Nothing is ever lost': as evolution proceeds, earlier stages are not undone or superseded, but only reorganized under new conditions.

The book also presented a threefold typology of societies, each with its own kind of religion, seen as the symbolic realm that secures ultimate meaning to social and political structures. Tribal societies are based on 'reverse dominance hierarchies,' in which a fundamental equality is maintained in the face of repeated attempts at imposing a full-fledged, vertical hierarchy. Upstarts are successfully kept at bay by mimetic religious rituals in which all the members of the tribe participate in order to reimpose again and again the power of society over its individual members and their disposition to dominate. Archaic societies are characterized by strong political centers, articulated systems of stratification, and complex cosmologies which make sense of the relationships between ever-growing pantheons of deities and society. The shift from tribal to archaic societies is possible only when divine kings succeed in having the whole of society focus its attention on them as the sole mediators between the divine and the mundane realms.

Axial religions are marked by the so-called 'axial break,' which Bellah reconceptualized as the emergence of 'second-order thinking,' understood as 'thinking about thinking' – that is, a reflection on the very bases of rational reflection. Often, but not always, axial religions are characterized by a radical cleavage between a transcendent and a mundane order, so that the status of truth and the authority of divine kings are put into question: 'Who is the (true) king, the one who really reflects divine justice?' Through the analysis of four case studies – Ancient Israel, India, China, and Greece – Bellah described the emergence of second-order thinking in religious and philosophical thought, and focused on those prophets, philosophers, and free-floating intellectuals who put themselves at the center of the axial break as the carriers of the higher truths of some universal ethics. In the concluding chapter, Bellah praised the critical and universalistic heritage of the Axial Age, but warned against the modern pretension to detach allegedly universal truths and ethics from practical and concrete forms of life.

Upon its publication, *Religion in Human Evolution* was acclaimed as a milestone in the historical sociology of religion. It received praise and critiques from scholars in various disciplines and was the subject of symposia and meetings in America, Europe, China, and Japan (see Stausberg, 2014). When Robert Bellah died on 31 July 2013 from the complications of heart surgery, he was writing one last book, tentatively titled *The Modern Condition in the Light of Human Evolution*. His work on civil religion, Japan, and religious evolution, and his understanding of the social sciences as public philosophy remain influential in both sociology and religious studies alike. In his last major intervention – the Paul Tillich Lecture at Harvard's Memorial Church in May 2013 – Bellah restated his critique of utilitarian individualism and the perils of the 'Protestant Principle.' But he concluded, speaking of Tillich notion of *kairos* as the possibility of something new in history, that "the *kairos* is now, always now. It is now that we are called to hope and to act."

Abstract

Reinhard Bendix was a German-born political sociologist whose work focused on industrial relations, nation-building, the history of ideas, the role of the social sciences in society, and the transformation of political legitimacy over time and across nations. He drew his inspiration from the work of Max Weber, one of sociology's founders, and was instrumental during the 1960s and 1970s in making Weber's vast and complex work accessible to English-speaking scholars. Bendix was a key figure in what has come to be called the 'first wave' of historically and comparatively oriented sociology in the United States, together with Seymour Martin Lipset (with whom he collaborated extensively; see Lipset and Bendix, 1953, 1959), and Barrington Moore.

Born in 1916, Reinhard Bendix grew up in Berlin. Thrown out, at age 17 years, of the academic high school he had attended, ostensibly because his classmates could not be expected to tolerate someone in their midst whose father had been arrested and taken into 'protective custody,' he spent the next years working as a clerk in a Jewish export firm in a Berlin growing increasingly oppressive to those of Jewish heritage. Emigrated colleagues of his father Ludwig, a well-known and widely published Berlin lawyer, were able in 1938 to obtain a visa for him that allowed him to emigrate to the United States. Despite his truncated secondary education, one of those colleagues secured admission for him to, and a tuition fellowship from, the University of Chicago, a university that would subsequently award Bendix his BA (1941), MA (1943), and Ph.D. (1947) in sociology. In 1947, he was offered a position at the University of California at Berkeley in the Sociology Department. He remained with the sociologists until 1972, at which point he decided to move a few floors up in Barrows Hall to join the political scientists.

His father Ludwig (Louis) Bendix left the Jewish community at age 20 years in 1897, embraced the German cultural norms of what it meant to be a cultivated, educated citizen, and did his best at home to pass this *Bildungsbürgertum* orientation, as well as his interest in social and political reform, on to his son. But Ludwig's utter commitment to the law (Bendix, L., 1968), which included defending communists in court, along with his outspoken opposition to what the Nazis were doing to the law and to the German state, brought about his repeated imprisonment after 1933, and his eventual permanent expulsion (including being stripped of his German citizenship) from Germany in 1937.

During his father's enforced absences in the difficult years between 1933 and 1938, Reinhard Bendix sought answers in meetings and discussions held by *Neu Beginnen* (a socialist-communist underground movement) and by *Hashomer Hatzair* (a socialist-Zionist secular Jewish youth movement), both Berlin groups that would be subsequently banned and their participants persecuted. As he reflected in the last two books he wrote, *Unsettled Affinities* (1993) and *From Berlin to Berkeley: German-Jewish Identities* (1986), neither left-wing ideology nor Zionism provided satisfactory answers to his questions, and throughout his life, Bendix remained acutely aware of his marginal status as an intellectual in an often antiintellectual American society, and as an heir to a religious tradition he did not and could not identify with. That personal disquiet was the starting point for rational analysis; both father and son shared a penchant for abstracting and objectifying their own situations (Bendix, 2004).

At Chicago, Reinhard Bendix found himself among professors (including Louis Wirth, Charles Merriam, and Leonard White) who were 'partisans of impartiality,' which he found exciting, as he wryly put it many years later, "because only a short time before I had experienced enough partisanship under the Nazis to be ready for a more rational approach to seeking knowledge" (Bendix, 1993: 11). Yet he found the sociological approach he learned at Chicago troubling, as it was inspired by the natural sciences and concerned with formulating hypotheses and subsequently trying to empirically verify or falsify them. While he was not averse to drawing on quantitative data (Bendix, 1949, 1956; Lipset and Bendix, 1959), for his taste such an approach seemed to rely too heavily on demonstration and not nearly enough on discovery and initial exploration, or even consideration of what was worth knowing. Reason mattered in social inquiry, but it should not be overshadowed by methodology or a blind adherence to forms of scientism. From his father, Bendix had also inherited an interest in the irrational foundations of rationality, and these various strands led to his MA thesis (Bendix, 1943) as well as to a number of sweeping essays later on the purpose of knowledge, the distrust of reason, the image of man, and the role of ideology (Bendix, 1984, 1988). Many of his concerns were expressed in his Presidential Address to the American Sociological Association in 1970 when he argued that an abiding faith in reason served as a counter to taking mindless action, and that it was important to protect a scholarly community that prized free discussion and independent inquiry.

When his *Work and Authority in Industry* (1956), a comparative and historical study of managerial ideologies, was republished in 1974, he wrote in a retrospective introduction that his impulse to conduct this study had arisen to counter the Marxist notion that ideas were simply epiphenomena of material production processes, and had not come about only due to his penchant for using wider frameworks than were common among his American colleagues at the time. At the

same time, the reasons employees subordinated themselves to the authority of employers were worthy of analysis, not least due to ideas prevalent in postwar America about rationality and efficiency in large-scale, hierarchically organized, economic enterprises. The comparative and historical vantage point employed in *Work and Authority in Industry* thus challenged received notions about rationality and subordination, and from a non-Marxist position, illustrated the relative autonomy of ideas and their use in managerial contexts.

Reinhard Bendix's experiences as a young man of the use and misuse of authority in a highly ideologically charged atmosphere were intellectually nurtured by Karl Mannheim's *Ideologie und Utopie* (1929) and Hans Barth's *Wahrheit und Ideologie* (1945). Coupled with his study of civil servants (Bendix, 1949), and then of managerial ideologies, this drew him to study Max Weber's work on domination and authority more intensively than he had previously. While not always agreeing with him (see Bendix, 1998), Bendix discovered an 'elective affinity' (*Wahlverwandschaft*) to Weber's work as well as to the comparative and historical methods Weber had used, and this deepened interest would lead him to publish *Max Weber: An Intellectual Portrait* (1960).

English translations of parts of Max Weber's vast oeuvre were available (Gerth and Mills, 1946; Henderson and Parsons, 1947), but no general road map, overview, or introduction to the entire body of Weber's work existed at the time in English. Reviewers were both grateful as well as effusive in their praise, with H. Stuart Hughes in the American Historical Review calling it "the full scale study that has long been needed" and an "extremely useful key" for those who wanted an introductory guide, as well as a "godsend" for students, while another reviewer in the American Anthropologist praised it as "an admirably straightforward exposition of the whole body of Weber's work." In his own introduction, Bendix self-deprecatingly noted that "the plain fact is that Weber's work is difficult to understand." Though he preferred to see himself as more of an interpreter than a proponent (Bendix, 1993: 12–14), publication of his intellectual portrait rapidly elevated him into one of the leading Weberians among sociologists.

But he was unwilling to be limited to only interpreting Weber, or to solely focus on industrial sociology, and thus turned to an examination of the global changes to political authority then underway: decolonization had meant 50 new states were added to the global map between 1944 and 1964. Many efforts to create different or new forms of state and society were underway, and such 'modernization' or 'economic development' processes were analyzed at length in works by Daniel Lerner, Rupert Emerson, Clifford Geertz, and Alexander Gerschenkron. Walt Rostow's stages of growth model, a five-phase scheme that ran from 'traditional society' through 'takeoff' to 'the age of high mass consumption,' was particularly influential. Bendix, however, remained skeptical of such interpretations, and was troubled by what often appeared to be neoevolutionary (if not teleological) assumptions in such works. Once a certain kind of social and political change had taken place, he argued, it could never again occur in exactly the same manner, so the path taken by European nations should not be seen as normative or determinative for the new nations of Africa and Asia. Historical experience was unique, limited, individual, and bound by space, time, and circumstance. His influential article 'Tradition and Modernity Reconsidered' (1967) was an early, explicit objection to the belief in the inevitability of 'modernization' trajectories.

His interest in transformation prompted him, in *Nation-Building and Citizenship* (1964), to examine these assumed 'Western' precursors of 'Third World' economic development in order to better understand what the conditions for political and social transformation might be. Drawing on the work of T.H. Marshall, and writing in collaboration with Stein Rokkan, he identified a key element of such transformations in the extension of civil, social, and political rights to previously excluded groups in European societies. This altered earlier relationships of dependence and fundamentally changed the roles the state and its civil servants, authority itself, would play. In *Nation-Building and Citizenship*, these insights were first used to discuss historical transformations in England, Western Europe, and Russia. Bendix then drew a more detailed comparison of the preconditions for the development of public authority in Japan and Germany, following it with a longer treatment of how public authority had emerged in the 'developing' political community of India. This work is clearly quite Weberian in inspiration, methods, and case selection.

In a very real sense, *Nation-Building and Citizenship* was a practice run for *Kings or People: Power and the Mandate to Rule* (1978). Published after 10 years' research, and a National Book Award finalist (1979; History), this was a sweeping examination of the development of political authority in England, France, Germany, Russia, and Japan. The first part of the book examined the sacred and secular basis for kingly rule through the early modern period; the second part, starting with the transformation of Western societies in the sixteenth century, examined the emergence of the modern nation-state in each of these five countries (there were also briefer consideration of the paths China and the Muslim world had taken). The book was exactly what the subtitle promised: an examination of what it meant to have a mandate to rule, both historically and comparatively, in the key countries that helped shape the world in which we now live.

Reinhard Bendix regarded intellectual work as a conversation rather than as a battle of egos and wills for dominance, an ongoing dialogue about matters of importance that was conducted between past, present, and future generations. The vital issues of the day certainly mattered to him, but so did the older, deeper discourses to which they belonged. That long, measured, European view prompted one of his long-time colleagues to once describe him as "an academic's academic."

When he liked a particular book (and many produced by Albert Hirschman fit that category), he would speak of "books to conjure with": it is safe to say that he produced several books like that himself. Bendix was also deeply involved in the university community that was his second home, not only in numerous administrative roles, but also as a committed and effective teacher whose graduate students would go on to hold significant professional positions in sociology, history, and political science. Yet in his view, the comity among colleagues and the productive intellectual ferment he had encountered in the United States in the postwar decades (as well as in the Western Europe he frequently returned to teach in as well as

earn several honorary doctorates from), had begun to wane and when he retired in 1986 he was grateful to gracefully exit from debates and intellectual discourses he no longer felt an affinity for. What he left behind were lasting intellectual bridges between Germany and the United States that emphasized an awareness of historical contingency as well as of the demonstration effects nation-states exerted on one another, and of the endless caution that is needed when attempting to generalize.

Abstract

A US cultural anthropologist Ruth Fulton Benedict is best known for two books, the 1934 *Patterns of Culture* and the 1946 *The Chrysanthemum and the Sword*. Each contributes importantly to the central premises of 'culture and personality' studies in US anthropology. Both books demonstrate the close connection between descriptive intensity and ethnographic reliability. Both, too, treat the theories and methods of a science in terms of their significance for ensuring human rights in any society. A foremost anthropologist, Benedict also wrote for a general audience, addressing the Great Depression, racism, and the rise of Fascism and Nazism in the 1930s.

A US cultural anthropologist Ruth Fulton Benedict is best known for two books, the 1934 *Patterns of Culture* and the 1946 *The Chrysanthemum and the Sword*. Each contributes importantly to the central premises of 'culture and personality' studies in US anthropology. Both books demonstrate the close connection between descriptive intensity and ethnographic reliability. Both, too, treat the theories and methods of a science in terms of their significance for ensuring human rights in any society. *Patterns of Culture* gave a wide audience a new concept of culture: an integrated and distinctive whole that molds the temperaments and talents of individuals. *The Chrysanthemum and the Sword* penetrated into the mechanisms through which 'culture' and 'personality' reinforce and replicate a dominant ethos. Both books assert the importance of individual creativity, a bow to the humanitarian impulse Benedict never lost.

The Life

Ruth Fulton was born on 5 June 1887, in New York City, the daughter of a Vassar graduate and a doctor of medicine. Two years after her birth, her father died and the vision of his lost opportunity for serving humankind haunted her for the rest of her life (Modell, 1983). After a childhood spent moving from city to city, in 1905 Ruth and her younger sister Margery entered Vassar College. After graduation, Ruth returned to her mother's house in Buffalo, where she worked for the Charity Organization Society of New York. The experience increased her sensitivity about her partial deafness and exposed her to the struggles of immigrant families in an industrial city. Dissatisfaction persisted, unresolved by teaching in a private school and living with Margery and her husband Robert Freeman in Pasadena, California. A marriage proposal from Stanley Rossiter Benedict seemed to resolve the doubts about her future. Like other women of her generation, Ruth hoped the role of wife would give her life a purpose.

A month after their marriage, World War I broke out. The crisis accentuated Benedict's despair at the limitations set for women, nonconformists, and outsiders in her milieu. She tackled the problem through essays on three 'rebellious' women, Mary Wollstonecraft, Margaret Fuller, and Olive Schreiner; never published, the manuscript reveals the writer's impatience with the conventions that restricted her own options. In 1919, Ruth Benedict enrolled in courses at the New School for Social Research, where encounters with sociologist Elsie Clews Parsons and anthropologist Alexander Goldenweiser transformed her thinking. A meeting with Franz Boas at Columbia University completed the process, and in 1921 Benedict enrolled in his anthropology program (*see* Boas, Franz (1858–1942)). A remarkable 2 years later, she received her PhD for a dissertation on 'The Concept of the Guardian Spirit in North America.'

During the 1920s, Ruth Benedict viewed her commitment to the discipline in the light of her quest for identity as a woman in the US society. Personal concerns provided an impetus for anthropological inquiries, while at the same time intervening on the path to a conventional academic career. During this period, too, the strains between her and Stanley increased, and in 1930 they agreed on a formal separation. By then Benedict had formed strong bonds with her student Margaret Mead and with Edward Sapir, her colleague. Conversations about the poetry all three wrote prompted Benedict to prove that anthropology could incorporate the voice she had developed as a poet. Her aesthetic principles contributed as much to her anthropology as the advice about culture and person offered by Boas.

Ruth Benedict took on teaching duties at Columbia, trained students for the field, and in 1924 assumed editorship of the *Journal of American Folk-Lore*, a position she held until 1940. External obstacles to success in academia became apparent when, after Boas retired in 1937, she did not receive the headship of Columbia's Anthropology Department. The appointment of the anthropologist Ralph Linton surprised her colleagues, seeming to many to indicate the continued discrimination against women in US society. In reaction to Linton's appointment, to her abiding restlessness, and to her equally abiding belief in the scientist's duty as citizen, Ruth Benedict moved to Washington to serve her government during the war. She died on 17 September 1948, in New York City, where she had returned. She was 61 years old and in the midst of formulating a major theory of self and society.

The Anthropology

The 1934 publication of *Patterns of Culture* placed Ruth Benedict in the forefront of American anthropology (*see*

Anthropology: Overview). The book pulled together ideas she had developed in earlier pieces: the significance of coherence and of integrating customs, the social construction of marginality and deviance, the uses of a comparative method for establishing a relativistic stance. In the book's five discursive and three ethnographic chapters, the anthropologist set the foundation for her theoretical and methodological contribution to contemporary social sciences.

The book is best remembered for the notion that 'culture is personality writ large.' The theoretical claim receives support in the ethnographic chapters, which treat three distinct cultures as unitary, integrated, and patterned entities with characteristic personalities. Benedict's concept of culture did not exclude individuals, but explained the links between person and group. The links, she wrote, could be harmonious, leading to the 'successful' individual, or they could be discordant, driving an individual into nonconformity, marginality, or madness. Three cultures form the triptych for an application of her theory, the Pueblos of the American Southwest, the Dobu Islanders, and the northwest coast Kwakiutl. Each of these cultures receives a 'tag,' the famous Apollonian, paranoiac, and megalomaniac designations that for many readers obscured Benedict's concern with the processes by which a cultural configuration comes into being, persists over generations, bends to change, or collapses under crisis.

Methodologically *Patterns of Culture* introduces interpretive techniques that remain significant to anthropological analysis today. Ruth Benedict's reluctance to spend time in the field went hand in hand with an imaginative reading of available evidence from disparate details of behavior reported to her by informants, stored in ethnographies, or enshrined in items of material culture. Constant reference to US culture further extends her method, drawing comparison away from a simple juxtaposition of traits and toward the assessment of diverse 'arrangements' that became central to her work of the next two decades. In *Patterns of Culture*, Benedict shows brilliantly how the social scientist can maintain relativism in description while taking a stand on the implications of an 'arc' of traits (1934: p. 24).

Over the next decade, she published articles on classic anthropological topics in the 1933 *Encyclopedia of the Social Sciences* and simultaneously probed into the causes and consequences of the Great Depression for a general audience. In periodicals like the *American Scholar* and the *Partisan Review*, she brought an anthropological perspective to the subjects of, for example, unemployment, the 'problem of youth,' and the value of freedom of speech. Drawing on her discipline's comparative method, she mounted a stern critique against the United States. She criticized her country for wasting the resources of its population, for discriminating against particular groups, and for nurturing neuroses in its citizens. Professional and popular pieces preached an enlightened social engineering that drew lessons from cultures in which no individual was denied social participation or deprived of fulfillment.

Benedict's inquiry into the patterns of American culture led her to take on issues of race and class – related, in her framework, to democracy and social justice. Consequently, she examined the spread of totalitarianism under the lens of a comparative analysis of institutions and ideologies that deny the humanity of selected groups. From her perspective, understanding the rise of Nazism and Fascism meant discovering the conditions under which individual citizens detect no disjunction between their commonplace assumptions and the dictates of a political ideologue.

On the eve of World War II, Ruth Benedict reconsidered the implications of cultural relativism and its nonjudgmental stance (*see* Cultural Relativism, Anthropology of). Like her mentor Franz Boas, she had argued that every culture should be treated in terms of its own values and purposes. By the end of the 1930s, she sought a scheme for evaluating cultures that respected difference while also disclosing the danger some arrangements clearly posed. Danger came in terms of the suppression of individual creativity, fulfillment, and satisfaction; danger came, more dramatically, in acts of murder and genocide. Reacting to world events, Benedict fashioned the material for a theory of self and society in three separate endeavors: an article on child rearing, a book on race and racism, and a series of lectures on the theme of 'synergy' (the effective integration of all aspects of society).

In 1938, Ruth Benedict published a seminal piece on child rearing, entitled 'Continuities and Discontinuities in Cultural Conditioning.' The article appeared in *Psychiatry*, a journal that fused psychiatry and social science (*see* Cross-Cultural Psychology). The piece reveals Benedict's ambivalence toward Freudian theory and her conviction that social conditions provide the framework for personality development. Her argument then sounds commonplace now: cultures should foster consistency between childhood and adulthood, so that traits learned early are appropriate to behaviors required later. At every turn, 'Continuities' criticizes US culture where, by contrast, dominant values result in sharp discontinuities between childhood and adulthood. The outcome, the anthropologist concluded, is the 'neurotic personality' Karen Horney described. Under ideal conditions in any culture, Benedict wrote, children are conditioned into responsible social participation, their capacities fully utilized.

Simultaneously Benedict struggled to satisfy the terms of an invitation to lecture on 'the individual and society' at Bryn Mawr College in February 1941. An opportunity to expand her theories, the forum challenged her to delineate systematically the relationships between individual capacity, favored temperaments, social institutions, and cultural values. By then, too, the anthropologist explicitly recognized the urgency of calculating "the consequences for human life of different social inventions" (1970: p. 322).

Only notes remain from these crucial and complicated lectures to show how far Benedict had moved from *Patterns of Culture*. The move took three forms: greater attention to the psychodynamics of personality development; an acute analysis of the institutions through which individual behaviors are organized; and an effort to develop a plan for social change that acknowledged the significance of customary beliefs and behaviors. She chose the word 'synergy' to represent the effective working together of parts, and she compared low synergy with high synergy societies. The lecturer praised 'high synergy' societies, in which cooperation is at a maximum and all acts are mutually reinforcing. In such societies, individuals achieve a strong sense of responsibility and well-being. The unanswered question appears as well: what factors produce high

synergy, which low synergy in a society? Her wartime writings pushed her closer to an answer.

A third endeavor refined Benedict's theory of self and society. In the 1940 *Race: Science and Politics*, Benedict analyzed discrimination and racism in her own society. She mounted her strongest attack against a presumed scientific fact of innate endowment, the rationale for prejudices that condemned 'Negroes' (in the language of the times) to marginal participation in US society (*see* Racism, History of). Using comparative examples as well as historical references, she accused her country of fostering divisiveness, crushing the will of individuals, and undermining its own stamina.

The book acknowledged a debt to Boas in insisting that anthropology turn its methods and theories to the solution of contemporary problems. War made the obligation crucial for Benedict, and in the winter of 1942 she assumed a position at the Office of War Information (OWI) in Washington, DC. Obituaries she wrote when Boas died, in December 1942, convey the viewpoint that brought her into the government: "He never understood how it was possible to keep one's scientific knowledge from influencing one's attitudes and actions in the world of affairs" (quoted in Modell, 1983: p. 274). In the OWI, Benedict pursued 'national character' studies; the last assignment put on her desk was 'Japan.'

"The Japanese were the most alien enemy the United States had ever fought in an all-out struggle." So reads the first sentence of Benedict's 1946 publication, *The Chrysanthemum and the Sword*. The wartime study validates the place Benedict already had in her discipline and indicates the directions she would have pursued had she lived longer than 2 years after the book's publication. The study of Japan continues the themes she raised throughout the 1930s: how to ensure the well-being of members of diverse cultures without violating the integrity of each culture, how to turn anthropology's comparative method to the service of international organizations devoted to peace, how to exercise responsibility as a social scientist without transgressing the rules of evidence and neutrality. The failings of the book, like its strengths, can be attributed to the complexity of Benedict's goals.

Despite thickly textured descriptions, the book is less an ethnography of Japanese culture than an expansion of anthropological method and theory. Benedict turned the impossibility of doing fieldwork into a virtue, stressing the importance of interpretation over immersion. The anthropologist, she wrote, "can draw up his hypotheses and get his data in any area of life with profit. He can learn to see the demands any nation makes, whether they are phrased in political, economic, or moral terms, as expressions of habits and ways of thinking which are learned in their social experience" (1946: p. 13). Her data are the 'commonplaces' any Japanese would recognize the behaviors and beliefs an ordinary person deems natural.

The result is a persuasive display of the dominant 'patterns' of Japanese culture without the homogenizing descriptive tag of her earlier efforts. Benedict shuns the isomorphism implied by 'culture and personality,' while recognizing the importance of consistency between 'society' and 'self' for maintaining high synergy. Japan in World War II was notably synergistic: every act and every attitude seemed to the observer–interpreter to flow harmoniously, the Emperor's commands coordinating with the motives and feelings of Japanese citizens. This was Benedict's test case, exemplar of the high synergy society she had praised in 1941. The book explores the processes through which personal impulses, tightly constructed cultural demands, and the needs of a nation are channeled smoothly together, without frustration or conflict.

Critics of *The Chrysanthemum and the Sword* gloss over Benedict's delineation of process, and mistakenly consider the designation of Japan as a shame culture the book's major thesis. In the study of Japan, however, *emotion* is an analytic concept that allows the anthropologist to link the drives of individuals to the maintenance of social order and cultural consistency. 'Shame' pushed Benedict's ongoing exploration of self and society into its most radical formulation yet, as she demonstrated the delicate and daily ways in which persons internalize the pressures of their surroundings without experiencing lethargy, anger, suffocation, or despair. Chapters display the abundance of reinforcing activities and attitudes that make shame both a powerful sanction and a barely perceptible burden for the Japanese individual.

Ruth Benedict bequeathed to social science a theory of the social construction and the social uses of an emotion. She argues that mechanisms for instituting and fostering an emotional pattern crucially support the contemporaneous conditions in which a society finds itself; change in the conditions can render the emotion dysfunctional – a conclusion she reached about Japan, as the nation encountered devastating defeat in the war. She vividly evokes the circumstances under which an emotional pattern wastes the resources and erodes the capacity for meaningful social action by individuals and institutions.

A comparison between Japan and the United States runs through the book, permitting a sophisticated analysis of shame and guilt that anticipates later recognition by social scientists of the twinning of these emotions. At the same time, Benedict's concern with the collapse in Japanese society after the war biases the comparison, so that shame comes to seem an immature and confining emotion. On a theoretical level, however, her discussion of emotion is value free. She does not posit a hierarchy, in terms either of human or social development, but rather assesses the function of an emotional configuration as it releases or represses the expression of human creativity – the humanism in her science.

An emphasis on the social construction of emotion completed Benedict's critique of Freudian theory. If individual emotions are socially constructed, then they are alterable through planning and careful calculation of conditions. Recognizing the complexities of this assumption, Benedict developed strategies for testing her theoretical premises in new settings. She undertook several projects after the war, including child rearing studies for UNESCO, participation in the US Navy's 'cultures at a distance' project, and further comparative inquiry into emotional configurations (*see* National Character).

The Accomplishment

Ruth Benedict's contribution to social science comes from her ability to combine critical theory with cultural relativism. She accomplished this by constructing a scheme for assessing

cultures in terms of the integrity of purpose and coherence of 'traits.' The scheme included inserting the 'human being' into an analysis of social structures in a way that foreshadows a theoretical framework dominated by the concepts of 'actor' and 'agency.' Benedict, however, did not simplify those concepts or use them to signal a desirable relation between 'person' and 'culture.' Rather, she construes 'actor' as constituted at once by idiosyncratic drives and by external shaping forces; she connects 'agency' to the possibilities of self-fulfillment and individual creativity. Her attempts to explore systematically the conditions under which the ensuing tension between self and society is productive rather than destructive banished the simplistic 'culture and personality' equation of earlier works. A founder of that subfield of US anthropology (*see* Anthropology, History of), Benedict insisted on the humanism that is key to contemporaneous research in diverse social scientific disciplines.

Inasmuch as her comparative analyses have at core the human being – creative, cooperative, resistant, rebellious – they impose a rigorous critique on all cultures. The body of her work asks, "does a particular social arrangement suppress or exploit diverse individual capacities?" The question pushes Ruth Benedict into the vanguard of critical social theory in two respects: she does not abstract the individual from the material conditions that govern social responsibility, and her emphasis on the diversity of purposes and temperaments in any setting anticipates a twenty-first century deconstruction of the concept of culture. Prefiguring her successors in the discipline, Benedict replaced the definition of culture as a static collection of traits with the notion of an open-ended, dynamic, and continuously created mode of life. Her bold move toward emphasizing the possibilities for an integrating culture, in which self and society evolve according to a dominant purpose, makes her work a model for today's interdisciplinary critical social theory. Moreover, the openness of her concept of culture broke down the boundaries between 'us' and 'them,' bringing the United States onto the same plane as the smallest tribal society.

Behind these innovative contributions lay Benedict's persistent commitment to the application of her discipline. While she embraced cultural relativism, she also insisted that the anthropologist interpret diverse cultures in terms of their benefits to the individual. She perceived no contradiction between 'neutral' research and a judgment of 'worth.' From her point of view, the findings of any science ought to be devoted to improving the human condition: preventing war, ensuring peace, and, above all, granting anyone in any milieu access to resources and to rights. Stressing the importance of directed change, Benedict did not preach an imperialistic social engineering. She argued instead that the social scientist had unique skills with which to delineate the cultural values and social institutions upon which change must be based in order to last.

In Ruth Benedict's writings, humanism extends from theory to methods of inquiry and styles of presentation. She knew, as poet and as anthropologist, the importance of writing, and her words carry her argument through evocation and nuance. In this, too, she anticipated a twenty-first century concern with disciplinary writing and the extension of anthropological findings to a wide audience. For Benedict the value of a social science lay in its persuasive embodiment of an ethical stance. Here again she makes a major contribution: writings that appeal to a general audience, to policy makers and to soldiers, to social scientists and to artists, presage a contemporary scholarship that refuses to remain in an ivory tower.

Abstract

Seyla Benhabib is currently one of the most prestigious intellectuals across the globe. She was born in Istanbul, Turkey, in 1950 and she was brought up within a multilingual context. Later, she moved to the United States of America to pursue her PhD and then to start her academic career. She received the intellectual heritage mainly from German thinkers such as Kant, Hegel, Arendt, and Habermas. Thus, Benhabib's work is an attempt to perform a review of the unfinished project of the Modernity. The article aims to draw an overview about the personal, intellectual, and professional life of Seyla Benhabib.

Introduction

Seyla Benhabib is currently one of the most prestigious and interesting intellectuals across the globe. She comes from Turkey where she spent her childhood and adolescence. She was brought up within a multilingual context, due to the fact that her nuclear family spoke several languages including Turkish, French, Italian, and Ladino. She was educated in English and American schools, thus English became her language of instruction. At the age of 20 she earned a scholarship to move to the United States of America (USA) in order to carry on with her university studies. Further on in time, she received a PhD at Yale University with a dissertation on Hegel's philosophy of right. Her works have been influenced mainly from German thinkers such as Immanuel Kant, Georg Hegel, Hannah Arendt, and Jürgen Habermas. In fact, she defines herself as a specialist on European and German thought (Kreisler, 2004).

Benhabib has taught in several universities in the USA including Yale, Harvard, and Boston, among others; she has also lectured in many different countries worldwide on relevant topics for both academic and general audiences. She also held visiting professorships and research fellow positions at many well-known universities and research institutions around the world. Furthermore, she has a broad intellectual production, which is mostly formed by scientific journal articles, books, and editions of books. To date, her work has been translated into at least 11 languages in which we can find German, Spanish, French, Chinese, Japanese, Turkish, Russian, Italian, Servo-Croatian, Hebrew, and Swedish. Along 35 years (and it continues), she has been performing a brilliant academic career, working as a professor at the most highly renowned institutions in the USA.

According to some scholars (Campillo, 2006; Sánchez-Muñoz, 2009; Fernández de Sevilla, 2011), Benhabib's work is an attempt to perform a review of the unfinished project of the Modernity. In this regard, her work shows long-standing concern and interest with the same basic question. That question addresses the reconciliation of fundamental universalistic principles, such as human rights, autonomy, and freedom, with the existence of specific identities as members of particular communities separated by language, ethnicity, and religion (Kreisler, 2004). Nevertheless, this main question was studied by Benhabib through different relevant topics, which were appearing to her throughout the years. She has been focusing on issues, such as Critical Theory, Deliberative Democracy, Law, Globalization, Cosmopolitanism, Feminism, Hannah Arendt's thought, Immigration, Ethnicity, and Culture, among others.

Indeed her work can be classified into three main stages due to those main topics of study (Sánchez-Muñoz, 2009). The first stage of her work began during the 1980 decade as a critique and reformulation of Critical Theory, especially around the theory of communicative action of Jürgen Habermas. The second one takes place in the 1990 decade when her work turned to a more empirical approach. In this stage, the main question is how that contextualized subject can be included in the specific liberal democracies without losing their own cultural identity. The last and current stage began in the beginning of the twenty-first century, when Benhabib started to analyze the existing tensions between the rights of the people who live in a globalized world but whose citizenships are, at the same time, fixed to particular territorial spaces.

Therefore, the aim of this article is to give an overview of the personal, intellectual, and professional life of Seyla Benhabib until today. The article uses the following structure. The present Introduction, i.e., this first section, contains the general ideas of the whole article. This is followed by the second section, which reviews Benhabib's family background and her childhood and youth in Turkey. Taking a close look at her personal and family background suggests how different issues could fit well into her research interests and political concerns later when she became an intellectual with a strong political commitment. The third section describes her education at Brandeis University and Yale University in the USA, and the academic positions that she held afterward. The fourth section deals with the issue about the political commitment of doing political philosophy and with the role of Benhabib as a committed intellectual. The fifth section is concerned with her research interests and her intellectual production, which are classified into three stages.

Multicultural Family Background, Childhood, and Youth in Turkey

Seyla Benhabib was born in Istanbul, Turkey, in 1950 within a Jewish family. Indeed she was raised within a multicultural and multilingual environment. At that time, Istanbul was (and still is) one of the largest cities in Europe, where a rich cultural diversity has assembled over several centuries. In fact, it was continuously the capital city of four empires, from the Roman Empire (330) until the end of the Ottoman Empire (1922).

Benhabib's family has a rich and interesting cultural background. Her ancestors were Sephardic Jews who came to Turkey in 1492 when the Alhambra Decree of the Spanish Kingdom forced the Jewish community either to convert to Christianity or to leave Spain. The Ottoman Empire was somehow open to receive that immigration in order to seize part of the eastern Mediterranean commerce.

Her nuclear family also has a quite remarkable story that could have strongly influenced Benhabib in several ways. On her father's side, though her grandfather was a rabbi her father could not complete his studies because he had to join the Turkish Army as soon as World War II started. However, he was released soon because Turkey remained neutral in the conflict until 1945. Then her father went into business. On her mother's side, her grandmother could neither read nor write, as she never had the possibility to attend school. Despite her grandmother's lack of education, Benhabib's mother was educated under French and Italian languages, due to the fact that she attended a French elementary school and later an Italian High School. After finishing high school, her mother got a scholarship in order to go to Italy to study History of Arts, but for family reasons she had to refuse the scholarship and stay in Turkey. A year later in 1939 her parents were married. Benhabib believes that her mother could not study further because of the circumstances of being a woman in Turkey at that time (Kreisler, 2004). Certainly, that fact could have had some remarkable influence in later Benhabib's concerns about the women's rights.

With this parental background, several languages were in use during Benhabib's childhood and youth. Her mother could speak French and Italian besides Turkish, of course. And Ladino, a Romance language spoken mostly by Sephardic Jews, was also used among the members of the family. So, as Benhabib said, they could easily change into each of those languages in different everyday-life situations (Kreisler, 2004). The English language appeared as soon as Benhabib went to high school. Benhabib was educated in an English speaking context since she attended the English High School for Girls for secondary school or junior high, and the American College for Girls for senior high education, where she received a Bachelor's degree in Philosophy in 1970.

The institutions she attended in Istanbul during her youth gave her the chance to get in contact with classmates from different countries, cultures, and religions as both schools were attended by children of an 'elite,' such as children of diplomats or teachers who were working in Turkey, among others. There were also locals with similar non-Turkish family backgrounds, including Armenian and Greek. Furthermore, there were teachers in the American College for Girls, who came to teach in Istanbul instead of going to the Vietnam War. They also brought with them political discussion during the 'lunch hours.' It was around 1968 and that time has been described by Benhabib as "a speedy process of politicization" (Kreisler, 2004). A bunch of events were taking place at that moment, the Vietnam War and the antiwar movement, the student movement with the 'French May' in France, and a remarkable workers mobilization in Turkey around the emergence of an independent left.

As a consequence, she was brought up within a tension between oriental and occidental values. In fact she was Jewish, that is, part of a minority within a primarily Muslim society, but she was also part of the European cultural heritage gathered through her formal and informal education. Therefore, the diversity in Cosmopolitan Istanbul, her family background, and her own personal life must have played a key role in shaping her views of the world, making her sensitive of issues and concerns highly relevant in her later career (Kreisler, 2004). Her personal background, along with the political mobilization around particular worldwide events during the 1960s and 1970s, such as the Vietnam War, the student's and the worker's movements, were surely fundamental experiences that affected her political thought and her intellectual production.

Higher Education Abroad and Academic Positions

After receiving her Bachelor's degree in Humanities at the American College for Girls in 1970, she moved to the USA to carry on with her university studies. She attended Brandeis University where she received a Bachelor's degree in Philosophy in 1972. Brandeis University closely related to the Jewish community and founded in 1948, was at that time one of the youngest private research universities in the USA. The possibility to study in that institution was given by a scholarship granted by the Wien International Scholarship Program (Kreisler, 2004), which is a need-based scholarship awarded to exceptionally international applicants who show strong academic achievement, significant community involvement, and demonstrated financial needs. This scholarship program had been running since 1958 with the aim of funding students from all over the world, who pursue undergraduate studies at Brandeis University.

This scholarship also represented the front door through which Benhabib entered to the American educational system. It would become a platform from which to jump to the highest university level worldwide, reaching Yale University to perform PhD studies and later to start her teaching career. However, when she arrived at Brandeis, it must have been a big shock for her since she was coming from one of the biggest and most cosmopolitan cities of Europe to study in a University located in the small town of Waltham, Massachusetts, with only 60 000 inhabitants.

Once she obtained her BA degree from Brandies, she moved to Yale University to pursue her PhD studies. After 5 years she received a PhD degree in Philosophy at Yale University in 1977. Her dissertation was on Hegel's Philosophy of Right under the title 'Natural Right and Hegel: An Essay on Modern Political Philosophy.' She was interested in Hegel's thought because the German philosopher was "one of the first systematic thinkers in modernity" (Kreisler, 2004), who pointed out the three

principles of the modern State: morality, legality, and ethical life. Those three principles and their particular interrelations have traced the path in which the thought of Benhabib has developed.

Benhabib has stated that she, since her PhD dissertation, has been involving the same central question in her further work. In this regard, she said that this question might not be related only to the research interests that a philosopher might have, but also to 'an existential question' that comes along in their philosophical work. To Benhabib the existential issue that already appeared in her dissertation and seems to remain through the years, deals with the reconciliation between basic universalistic principles, such as human rights, autonomy, and freedom, and specific identities as members of particular communities (Kreisler, 2004). Though an existential question, there are different ways to study the same research object, as she has shown when she changed the direction of her work during the 1990 decade (Wahl-Jorgensen, 2008; Sánchez-Muñóz, 2009). Her work will change the direction again during the 2000 decade (Sánchez-Muñóz, 2009), which will be further discussed in the last section.

Immediately after receiving her PhD in 1977, Benhabib began her teaching career at Yale University, where she joined the Department of Philosophy for 2 years, as an Assistant Professor of Philosophy. Then between 1979 and 1981, she was an Alexander von Humboldt Research Fellow at the Max Planck Institute in Starnberg, Germany. After that she had a position for 4 years (1981–85) at Boston University as an Assistant Professor of Philosophy at the Department of Philosophy. Subsequently she became Associate Professor of Political Theory at Harvard University between 1987 and 1989, Associate Professor of Philosophy and Women's Studies at State University of New York at Stony Brook for the period 1989–91, and finally Professor of Political Science and Philosophy at the New School for Social Research during 1991–93.

Then between 1993 and 2001, she returned to Harvard University, however, this time, she became a Professor of Government in the Department of Government at that institution. At the same time, she was a Senior Research Fellow at the Center for European Studies at Harvard. Also in 1996, she was a Visiting Senior Fellow at the Institute for Human Sciences (Institut für die Wissenschaft vom Menschen, IWM) in Vienna, Austria. From 1997 until she left Harvard in 2001, she further chaired The Committee on Degrees in Social Studies at Harvard. That committee promotes the interdisciplinary concentration of social theory, history, and culture at undergraduate level in order to analyze social, political, and economic problems confronting contemporary societies.

In 2001, she was endowed with a Eugene Meyer Professorship of Political Science and Philosophy from the Department of Political Science at Yale University. Moreover, between 2002 and 2008 she was the Director of the Program in Ethics, Politics, and Economics at Yale. This Program promotes the interplay among empirical, analytical, and normative concerns from different disciplines related to Social Sciences and Humanities. Taking into account the current complex social realities, the program was designed to promote well-founded debate about public policy in view of the reflection on the essentials of human association. From January to July 2009, she was also a Senior Fellow at the Institute for Advanced Studies of Berlin (Wissenschaftskolleg zu Berlin).

Furthermore, Benhabib has been recently awarded with honorary degrees and several prizes. She holds honorary degrees from the University of Utrecht (2004), University of Valencia (2010), and Bogazici University in Istanbul (2012). During 2011–2012, she was a Guggenheim Fellow and Straus Fellow at New York University's Straus Institute for the Advanced Study of Law and Justice. Due to her contributions to ethics and political theory, Benhabib was also awarded in 2013 with the Meister Eckhart Prize of the University of Cologne and the Identity Foundation in Germany. In May 2014, she received an Honorary Doctorate of Humane Letters from the Graduate School of Arts and Science at Georgetown University.

The Political Commitment of Doing Political Philosophy

The aim of this section is to consider Seyla Benhabib as a committed intellectual of our time. Indeed, she has shown a strong political commitment in her career, which is widely demonstrated throughout her intellectual work, civic activities, and lectures given around the world. An important example of her civic engagement is the organization of the 'Istanbul Seminars: Close encounters across all divides,' in which Benhabib, together with other scholars and intellectuals (Giancarlo Bosetti, Alessandro Ferrara, Abdou Filali-Ansary, Nina zu Fürstenberg, Nilüfer Göle, Ferda Keskin, Nadia Urbinati, and David Rasmussen) has been participating in as a member of the Executive Committee since 2007. These seminars take place every year in Istanbul with the support of the 'Foundation Reset-Dialogues on Civilizations (Reset-DoC),' in which Benhabib also carries out the Chair of the Scientific Committee. The aim of the Istanbul Seminars is to bring together thinkers from different cultural backgrounds in order to discuss and debate the prospects for democracy, human rights, and religion within the current global society.

Recently, Benhabib has been awarded with two remarkable prizes due to her dedication and contribution to promote intercultural dialogue and understanding in the context of the global civilizations. The first one is the Ernst Bloch prize that was given to her in 2009 by the *Ernst Bloch Zentrum* of the city of Ludwigshafen am Rhein, Germany. The second one is the Leopold Lucas prize that was awarded by the Faculty of Protestant Theology at the University of Tubingen (Germany) in 2012. Furthermore, Benhabib was invited by the United Nations Democracy Fund (UNDEF) to serve as an individual member on the UNDEF Advisory Board for the period 2010–11. She accepted the honored invitation under the belief that democracy as a global project must be strengthened through the work of civil society organizations worldwide.

As Benhabib has already said, her interest in philosophy was always related to the fact that doing philosophy is a way of thinking about how certain abstract principles are currently "at work, or play themselves out in the course of history" (Kreisler, 2004). In this regard, it is worth mentioning, on the one hand, what being an intellectual means and what is the role of intellectuals in the (world) society in which they live, according to some relevant scholars to the subject. On the other hand, it

takes into account what Benhabib considers about her own work and function as a political philosopher.

According to Bauman (1987: p. 2), the term intellectual is used to describe those who "rise above the partial preoccupation of one's own profession or artistic *genre* and engage with the global issues of truth, judgment and taste of the time." In this sense, Shils (1971) argues that an intellectual is someone who, when participating in a tradition becomes the spokesperson of a particular knowledge. One of the main tasks of the intellectuals, following Shils, is to criticize the traditional beliefs upon which the social organization has been built. In addition, Coser (1968; Isola, 2013) points out that being an intellectual implies the manipulation of ideas and symbols, with the aim to criticize and modify them, to rearticulate them later in a specific *ethos* in order to share and defend them, and certainly to deny them to *others*.

A few years ago in an interview given to Harry Kreisler (2004) in the context of the 'Conversations with History' series of the Institute of International Affairs at the University of California (Berkeley), Benhabib clearly stated that in her opinion, being a political philosopher is 'more a vocation than a career.' In that sense, political philosophers can work at different places doing a variety of activities, such as teaching and researching at universities, being journalists, or even human right activists. Following this distinction, we have to take into account the difference between the terms intellectuals and experts. The latter refers to a 'socioprofessional category,' which means that an expert is someone who can solve specific problems in the path to reach a purpose, according to a particular technique, which is linked to a specific field of knowledge. On the contrary, the term intellectual refers to someone who defines himself some ideals and objectives related to the good of a community. Those objectives are built on its 'symbolic knowledge,' which is based on universal principles. According to that, the main function of an intellectual would be to participate in the public sphere to criticize everything missing in order to reach those ideals (Isola, 2013).

In this regard, following Benhabib's points of view, a political philosopher might have 'a vocation for thinking' about the 'phenomenon of the political.' She points out here that there is an important current of thinking within political science that understands the phenomenon of the political mainly as 'a strategic bargaining of various games,' through which various groups try to get different benefits of any kind, either power, money, or authority. Instead, Benhabib claims for a somewhat more anthropological definition of the phenomenon of the political whereby the political must be understood as the way that "all communities of any degree of complexity organize themselves according to certain principles of justice, equality, reciprocity, and authority" (Kreisler, 2004).

Benhabib stated that doing political philosophy is to deal with particular realities in terms of 'what we are doing' or 'where we are going' according to certain abstract political principles. It is necessary, following Benhabib, to have dedication and passionate involvement in order to bring those principles to the concrete world (Kreisler, 2004). Just a look at all her work can make one realize that she has been pursuing that kind of political philosophy along her entire career. All her writings and lectures are contributions to think about our current democracies from an innovative and critical prism, which is what an intellectual must do.

According to Benhabib (1992; Fernández de Sevilla, 2011), philosophy has the special task to criticize the concepts upon which the beliefs and actions of our society are built. In this regard, Benhabib points out the necessity to perform a theoretical exercise, known as 'social exile,' through which philosophy could have the point of view from outside the mauls and borders of a particular society. It is arguable that her family background and her personal experience during her childhood and youth that made her politically conscious at an early age, and this has certainly been relevant to her intellectual and philosophical activity. Benhabib herself has stated that according to her biographical background, she always had "the sense of being in Turkey but not really being Turkish in the ethnic or national sense, and negotiating those conflicts as [she] was growing up" (Kreisler, 2004).

In the opinion of Fernández de Sevilla (2011), the philosophy of Benhabib is built upon "a model of public moral and political dialogue, free and egalitarian," in which "the elements of uncertainty, change or mobility" perform a noteworthy role. In that sense, Benhabib points out the impossibility to take into account fixed certainties, due to the fact that the fragility of the political institutions and the unpredictability of the practices of governance have frequently been shown throughout the history. Therefore, following Fernández de Sevilla, the political philosophy of Benhabib is based on the concepts of 'deliberation and democratic dialogue.' Indeed, Benhabib believes that only if we understand the conditions of others who might be fundamentally different from us, can we widen the boundaries of our sympathy with them (Wahl-Jorgensen, 2008) in order to build a pluralistic society.

Research Interest and Intellectual Production

Seyla Benhabib's intellectual production is broad, including journal articles, books, and edited and coedited volumes. Some of Benhabib's journal articles can be downloaded for free from her personal Web site at Yale University; two public lectures and an interview (the latter was already cited in this article) can also be seen online. Through her entire work, Benhabib has focused on issues such as Critical Theory, Deliberative Democracy, Law, Globalization, Cosmopolitanism, Feminism, Hannah Arendt's thought, Immigration, Ethnicity, Culture, among others. In the opinion of some scholars (Campillo, 2006; Sánchez-Muñoz, 2009; Fernández de Sevilla, 2011), Benhabib's work can be seen as an attempt to perform a review of the unfinished project of the Modernity. In this regard, her intellectual production deals with the challenges, with which the concept of universalism conceived by the deliberative democracy theory must confront within the new frame of the Globalization phenomenon.

According to Sánchez-Muñóz (2009), Benhabib belongs to the 'third generation' of Critical Theory, which reelaborates and widens the contributions of the 'second generation' mainly around the ideas of Jürgen Habermas. In terms of Shils (1971), Benhabib embraces that 'tradition' of this philosophical current of thinking, within which she shaped her own theoretical and analytical perspective. Throughout her works, she had been

continuously improving that 'inherited pattern of beliefs' by intending to solve new problematic phenomena derivative from the Globalization phenomenon and its varied consequences.

In this regard, the works of Benhabib have criticized and revised fundamental concepts forming the discourse of ethics and the theory of communicative action (Campillo, 2006; Bracci, 2002). To Benhabib (1994) the principle of universalism implies that human beings, due to their humanity, are entitled to 'moral respect from others,' which means they possess the undisputed entitlement to equally enjoy basic human, civil, and political rights. Therefore, her work shows a long-standing concern and interest about the same fundamental question. That question addresses the reconciliation of essential universalistic principles, such as human rights, autonomy, and freedom, with the existence of specific identities as members belonging to particular communities separated by language, ethnicity, and religion (Kreisler, 2004).

Following Sánchez-Muñoz (2009), the intellectual production of Benhabib can be classified into three stages. The first stage of her work began during the 1980s as a critique and reformulation of the Critical Theory, especially around the theory of communicative action of Habermas. Then she provides the Habermasian model with a 'contextualized subject.' The second one takes place in the 1990s when her work turned into a more empirical one. In this stage the main question is how that contextualized subject can be included in the specific liberal democracies without losing their own cultural identity. The last and current stage began in the beginning of the twenty-first century, when Benhabib started to analyze the existing tensions between the rights of the people who live in a globalized world but whose citizenships at the same time are fixed to particular territorial spaces. Her aim is to include the culturally excluded voices through the practice of the citizenship rights in the public sphere.

Three fundamental books of Benhabib belong to the first stage. Her first book is 'Critique, Norm and Utopia,' which appeared in 1986 and contains a strong critique to Critical Theory, focusing on Habermas' work and the concept of universalism. The second book, published in 1992, is 'Situating the Self' and proposes a reformulation of the Habermasian model, providing it with a 'contextualized subject.' In this regard, this work intends to perform a dialogue between the universalism of Modernity and its critiques coming from different currents of thinking, such as the communitarianism, feminism, and postmodernism, in order to produce a new form of universalism: the 'interactive universalism.' The third book is 'The Reluctant Modernism of Hannah Arendt' and was published in 1996. This book also represents a bridge between the first and the second stage of Benhabib's intellectual production.

According to Sánchez-Muñoz (2009), Benhabib finds in Arendt's works the foundations to carry out the reformulation of the Habermasian model of deliberative democracy. A communicative action is also a narrative action, which means that the identity of the subject and its actions are inserted in a 'web of narratives,' i.e., a 'web of interpreted relationships and stories.' Benhabib introduces a 'narrative turn' to the Habermasian model, conceiving human beings as 'story-telling animals.' Thus, Benhabib (1994) proposes the model of the 'moral conversation' in order to achieve reversible perspectives, which permit to understand the conditions of others who might be fundamentally different than one. According to that, Fernández de Sevilla (2011) states that the concepts of "deliberation and democratic dialogue" are the cornerstones, upon which the thinking of Benhabib is built.

During the 1990s Benhabib's work has experienced a significant change of direction, from studying the history of political thought to applying political philosophy to the present time. Therefore, she took a more empirical focus by looking at, and participating in, some concrete and contemporary discussions around new dilemmas that universalism must confront. She began working with issues, such as immigration, citizenship, women's rights, and multiculturalism, which became both academic and politically relevant with regard to the emergence of the European Union (Wahl-Jorgensen, 2008; Sánchez-Muñoz, 2009).

At the beginning of the twenty-first century another fundamental book was published: 'The claims of culture.' Here Benhabib (2002) observes that the unstoppable movement of people crossing state borders and experiencing different European cultures has a counterpart in the revitalization of local cultures. As a consequence, the claims to identity of different cultural groups have forced a rethinking of the concept of citizenship within the context of liberal democracies. How to handle the mixture and exchange of cultures and conflicting interpretations is one of the current challenges that European democracy must face in order to ensure a common future (Gutmann, 2003).

Thus, the third stage in the intellectual production of Benhabib takes place within the current globalized scenario, which involves the appearance of new dilemmas to the reformulation of the deliberative democracy model carried out by Benhabib. In this regard, the new challenges, to which this model must face, are the demands of a 'globalized universalism,' the spread of the 'moral conversation' to the entire humanity, and the building of a 'postnational solidarity project.' All of that is represented by those who are considered foreign elements to a particular nation or society, among which one can find immigrants, refugees, stateless people, and foreigners in general. Thus from a postnational approach, Benhabib outlines the principles of a cosmopolitan theory of justice, which centers on the principles and practices as a member of a political and legal community (Sánchez-Muñoz, 2009; Osborn, 2010).

During that period, the following two relevant books were published. The first one is 'The Rights of Others: Aliens, Residents and Citizens,' appeared in 2004. Here Benhabib states an interesting concept of citizenship as a 'social practice.' In this regard, following Fernández de Sevilla (2011), citizenship is more a pragmatic ability than an essential quality of the human beings. Thus, citizenship is the process and result of the political exercise carried out by the individuals in the public sphere. As a consequence, the notion of citizenship would no longer be attached to a fixed identity, because this identity could change through political practice. In the second book, 'Another Cosmopolitism,' Benhabib (2006; Sánchez-Muñoz, 2009) continues with her analysis concerning the 'processes of democratic iterations,' through which different members of the civil society can renegotiate the universal rights of belonging in both, legal and political

institutions, and civil society associations, within a new cosmopolitan social context.

Conclusion

Throughout this article Seyla Benhabib can be seen as one of the most important living intellectuals of our time. This has been widely demonstrated by her distinguished academic career, her strong political commitment, and her broad intellectual production. Benhabib's original point of view would be partly explained by her own condition as a person who was raised within and was influenced by a rich multicultural context. This background inevitably gave her a somewhat privileged critical view. On the one hand, she performed a reformulation of the theoretical framework derivative from the 'third generation' of Critical Theory and its critics. On the other hand, she deals with highly relevant issues to the building of a pluralistic democracy system in the context of the globalization phenomenon. Benhabib's works should surely be taken into account to better understand current democratic societies, especially those, like the European democracies, that are facing a relevant flux of people coming from different political and cultural environments.

Bentham, Jeremy (1748–1832)

Abstract

Jeremy Bentham (1748–1832) was educated at Westminster, Oxford, and Lincoln's Inn. From an early age he rebelled against the complacency, complexities, and injustices of English law. After a short period in practice, he devoted himself to reasoned criticism and reform of the law on the basis of 'the greatest happiness principle.' Bentham made significant contributions to philosophy, logic, penal reform, social policy, and democratic theory. But nearly all his main ideas stem from juristic concerns. Apart from unsuccessful attempts to promote his scheme for a model prison (panopticon) and his services as 'legislator for the world,' Bentham concentrated on writing. He was enormously prolific, but much of his work was not published in his lifetime. The *Collected Works* will fill a projected 70 volumes, of which 30 had been published by mid-2014. Work on Bentham texts has been accelerated since 2010 by an international project for transcribing and digitizing the hitherto unpublished articles. Bentham's jurisprudence is based on five pillars: the principle of utility; the theory of fictions (ontology and epistemology); the command theory of law; a comprehensive set of codes (the pannomion); and his constitutional theory. He was a follower and critic of Adam Smith in economics, a pioneer in promoting the collection of statistics, a strong legal positivist, a lifelong critic of natural law and natural rights, and a radical democrat. The picture of Bentham that is emerging from recent scholarship presents him as more complex, subtle, and genuinely radical than earlier representations.

Life and Writings

Bentham's father was a prosperous attorney. Hoping that his precocious child would have an illustrious legal career, he had him educated at Westminster, the Queen's College, Oxford, and Lincoln's Inn (called to the Bar in 1769). For Bentham each of these three institutions came to epitomize aspects of the prevailing orthodoxy: conservatism, complacency, hierarchy, superstition, insincerity, and the elevation of authority over reason. As a child, he conceived a passionate antipathy to the inadequacies and injustices of English law and procedure. Later, "English common law and equity seemed to Bentham archaic, uncodified, incomprehensible, arbitrary, irrational, cruelly vindictive, tortuously dilatory, and so ruinously expensive that nine out of ten men were literally outlawed" (Mack, 1968: p. 55). He very soon abandoned legal practice in disgust. Unmarried, and comfortably off, he devoted himself to criticism and reform of legal, political, and social institutions on the basis of utility or 'the greatest happiness principle.'

Bentham's most important diversion from writing was his attempt to lobby the government for a contract to design and manage a model prison, the panopticon. His proposals to William Pitt in 1791 received some encouragement, but then encountered repeated delay and opposition. The project failed, in the process nearly bankrupting him, alienating him from the establishment, harming his reputation with posterity, and pushing him toward democracy. He was eventually granted a sum in compensation for his efforts and expenses in 1813, but the project was effectively dead by 1803. Thereafter, he stayed mainly at home, or in various retreats, writing, conversing with his friends, acolytes and other visitors, and conducting an extensive international correspondence. When he died, he left approximately 70 000 pages of article, mostly unpublished.

Bentham was a secular child of the Enlightenment. The principle of utility came mainly from Helvetius and he owed much to Bacon, David Hume (*see* Hume, David (1711–76)), John Locke, Priestley and European thinkers, including Voltaire, Beccaria, and Charles Montesquieu. But he differed from his predecessors in several respects. He insisted that 'the art-and-science' of legislation required as preliminaries exhaustive taxonomy based on precise concepts and exact analysis of social facts. He had an acute awareness of the importance and limitations of language as the main instrument for expressing abstract ideas, and applied his version of utility and relentlessly detailed analysis to a remarkably wide range of subjects. He adopted clear, often extreme, positions on some issues. For example, he maintained that the only criterion of good and bad, of right and wrong, is the principle of utility; all other criteria are either meaningless or perversions of utility or utility disguised or pure subjectivism; that it is easier to justify torture than punishment; that talk of natural rights is both nonsensical and dangerous; that no artificial rule of evidence can promote rectitude of decision; that the common law is not really law, but a fiction based on judicial usurpation of power; and that the interests of the legal profession and of those in power are in general opposed to those of the community.

Despite this seeming clarity, many of Bentham's ideas invite conflicting interpretations. 'Benthamic ambiguity' is an important thread in reading Bentham. For example, he is often treated as a forerunner of both *laissez faire* and the modern welfare state, yet he does not fit either; he was a genuine political radical, but he placed a high value on security, and on the protection of existing property entitlements; he favored both strong government and strong democratic control; he virulently rejected most features of the common law, yet defended some salient institutions such as orality and cross-examination; the great codifier opposed all binding rules of evidence and procedure. There is no more ambiguous symbol than 'the auto-icon,' Bentham's skeleton, fully clothed and

topped with a wax head, that sits enigmatically in public in a cupboard in University College London, stimulating endless speculation about its possible meanings. Some seeming ambiguities can be resolved textually; some suggest honest and perceptive puzzlement; others hint that behind the benign exterior lay some deep inner conflicts.

Bentham as Jurist

Bentham explicitly aspired to be to jurisprudence what Luther was to Christianity and Newton was to science. His contributions to philosophy, political theory, and social reform were offshoots of his concern with law. Utility was a tool for both criticizing existing laws and institutions and guiding legislation. His ideas on linguistic analysis, on evidence and inference, and on democracy grew out of specifically juristic concerns.

Jurisprudence is the most extensive, original, and neglected part of Bentham's legacy. Yet he is better known as a philosopher, political theorist, and social reformer, for three reasons: few Bentham scholars have been jurists; many of the legal writings have only recently started to become accessible; and Bentham's disciple, John Austin, was for a century treated as 'the Father of English Jurisprudence.' Austin's command theory of law is inferior to Bentham's, but Austin was preferred because he was more sympathetic to the common law, less critical of the legal profession, and less dangerously radical than his master. His general ideas were also easier to grasp and to criticize.

Bentham's science of legislation is based on five main pillars: the greatest happiness principle, the theory of fictions, his positivist command theory of law, the pannomion, and, as a late but crucial addition, his constitutional and democratic theory.

Bentham as Utilitarian: The Greatest Happiness Principle

Bentham's best-known expositions of utility are in two early works, *A Fragment on Government* (1977, hereafter *Fragment*), first published in 1776, and *An Introduction to the Principles of Morals and Legislation* (1996, hereafter *IPML*), first published in 1789. The former is primarily an attack on the complacency of William Blackstone's idealization of the common law and his espousal of natural law and social contract theory at the start of his *Commentaries*. *IPML* was conceived as a prolegomenon to a penal code dealing especially with the classification of offences and the principles of punishment. The opening words of *IPML* are "Nature has placed mankind under two sovereign masters, *pain* and *pleasure*. It is for them alone to point out what we ought to do, as well as to determine what we shall do."

As a utilitarian Bentham is generally regarded as more representative than original. The rhetorical opening of *IPML* is often treated as epitomizing classical utilitarianism, a vehicle for considering standard criticisms on, for example, promising, punishment of the innocent, torture, and egoism. However, not all such objections apply to Bentham. For example, pleasure refers to all human values, not just to sensual or hedonistic pleasures or to wealth; the felicific calculus was not intended as an exact measure, but rather as providing a checklist of factors relevant to weighing the costs and benefits of any action; every individual equally counts for one, but the ultimate test is aggregate happiness (i.e., the general welfare). 'Extent' (whose happiness is to be taken into account?) applies not just to humans, but to all sentient beings, for in respect of animals "the question is not, Can they *reason*?, nor can they *talk*?, but can they *suffer*?" (*IPML*, 1996, Chapter XVII: pp. 282–286).

The first six chapters of *IPML* are not fully representative of Bentham's utilitarianism, as it developed over time. They are pedagogically convenient, because they are easy to read and to criticize. Here Benthamic ambiguity seems to begin at the very root of his thought: Does pleasure refer to satisfaction or to preference? Was he a direct or an indirect utilitarian? How different was Bentham's utilitarianism from Hume's? Does rooting utility in human nature make Bentham a closet natural lawyer? Do Bentham's utilitarian actors maximize their own pleasure or is every human choice, in individual morality and collective decision making, to be judged by its tendency to maximize the general welfare? Is the primary concern of sovereigns, their subordinates, and individuals rightly confined to one's own community, subject to certain exceptions?

Such questions are much debated. It is dangerous to impose on Bentham ideas that emerged in later debates about utilitarianism, for example, modern distinctions between act-utilitarianism and rule-utilitarianism, between preference and satisfaction, or between aggregate and average utility. Bentham's ideas developed over time and he was not always consistent. He might also have rejected sharp versions of these distinctions as false dichotomies.

Bentham's utility is a principle of both individual psychology and of social and political morality, of morals and legislation. For the jurist, the latter is both more important and less vulnerable to criticism. Humans generally seek to maximize their own interests, and the primary task of legislation is to harmonize individual interests with the general welfare by a system of rewards and punishments. Similarly, the interests of the governors need to be harmonized with the interests of the governed, especially through systematic design and implementation of securities against misrule. Bentham rejected any idea of principles independent of utility, but gave an important place to four principles subordinate to utility: security, subsistence, abundance, and equality. Of these security, or settled grounds of expectation, was the principal one because it implies extension in point of time and is a precondition for achieving the other ends of government. Bentham gave a high priority to both property and order, and hence for liberty in the sense of absence of coercion. Security is also the basis for the important motto of the good citizen, "To obey punctually; to censure freely" (*Fragment*, Preface). But security can be overridden by utility in given circumstances. Security and subsistence generally have a higher priority than equality, but in the calculus each individual counts for one, the idea of diminishing marginal utility serves as a distributive function, and Bentham believed that as a psychological fact "the nearer the actual proportion approaches to equality, the greater will be the total mass of happiness" (*Civil Code*; Harrison, 1983: pp. 243–250).

The originality and interest of Bentham's utilitarianism lie mostly in his *applications* of the basic ideas. Utility gives coherence and bite to his detailed treatment of evidence, classification of crimes, the rationalization of punishment, and numerous other specific topics. His utilitarianism should be

judged as much by its potential for illumination as an analytical and critical tool applied to concrete issues as by its philosophical defensibility.

Fictions

Bentham's theory of logic and language anticipated key later developments in English analytical philosophy, including the idea that sentences rather than words are the primary unit of meaning. To clarify basic abstract legal conceptions, such as 'obligation,' 'right,' and 'property,' he substituted for the traditional definition *per genus et differentiam* the techniques of 'paraphrasis' and 'phraseoplerosis.' Abstract nouns with no direct counterpart in the world of fact are names of fictitious entities. They can be elucidated by placing them in a whole sentence, such as "X has a right against Y," and then asking under what conditions this sentence is true. It is true if Y has a duty. "Y has a duty" is true if the sovereign of an existing legal system has commanded that there shall be a sanction (pain) for nonperformance in given circumstances, and Y's situation is subsumed under this command. Thus the terms 'right' and 'duty' are linked through 'sovereign' and 'sanction' to pains and pleasures, things that can be directly experienced.

Bentham's theory of fictions contains his basic ideas on ontology, epistemology, and logic. We construct our knowledge of the world through the lens of language, itself a human construct, which is both necessary because it is our window on the world and dangerous because it is a distorting lens. Language is the best tool we have for knowledge and understanding. This constructivist epistemology based on utility has affinities with later developments in pragmatism and the sociology of knowledge.

Bentham often used 'fiction' pejoratively. He attacked natural law, social contract theories, and technical legal fictions as dangerous mystifications. One example is his famous attack on natural rights as pestilential nonsense: to say that "X has a right" logically implies some existing general rule or command. "X has a legal right" presupposes a law commanded by a sovereign and backed by a sanction. Legal rights are creatures of positive laws. But since natural law does not exist nor do natural rights. The idea of natural rights is nonsensical, like the idea of a son without a father. To talk of imprescriptible (i.e., unalterable) rights is also meaningless, 'nonsense upon stilts,' for the sovereign's power cannot be legally limited. Since rights conflict, talk of 'absolute' rights is contradictory. Talk of nonlegal rights is also mischievous, raising expectations that cannot be fulfilled, inviting anarchy. Bentham's objections relate to the mode of discourse rather than to particular values. There may be moral claims and legal rights based on utility. He would not necessarily have opposed all modern legal bills of rights. His objection was to talk of nonlegal rights, not to the enactment into positive law of enforceable legal rights. A modern Benthamite can argue that talk of "a right to food" or "a right to work" refers to important aspirations, but begs questions about the allocation of correlative duties, about enforcement if not legally binding, and about the feasibility of implementing such 'rights.' They represent wishful thinking. As Bentham put it: "Want are not means: hunger is not bread." (Bentham, 2002: p. 330). Bentham started a line of analysis of 'rights,' 'powers,' and 'obligations' that was developed by Austin, Hohfeld (*see* Hart, Herbert Lionel Adolphus (1907–92)), Hart, and others. He still poses a challenge to loose rights talk.

Theory of Law

Bentham's legal theory operates on at least three levels: first, his general theory of law and its philosophical underpinnings; second, subtheories on, for example, codification and nomography, constitutional law, punishment and reward, and adjective law; third, the pannomion, a comprehensive body of codes of general application, subject to particular, essentially minor, modifications according to time, place and social context.

Bentham's jurisprudence starts with a strong positivist distinction between law as it is and law as it ought to be. "To the province of the *Expositor* it belongs to explain to us what, as he supposes, the Law is: to that of the *Censor*, to observe what he thinks it ought to be" (*Fragment*, 397). Exposition can be particular or general; censorial jurisprudence is general. Bentham's main interest was in universal censorial jurisprudence.

The fullest account of Bentham's general theory of law, *Of Laws in General* (1970 hereafter *OLG*), was first published in a definitive edition, edited by H.L.A. Hart, after Hart's *The Concept of Law* had become the leading text of English legal positivism, partly through its critique of Austin's imperative theory. Ironically, Hart conceded in a late essay that Bentham's version contained an important core of truth, "the notion of a content-independent, peremptory reason for action" as part of the general notion of authority (Hart, 1982, Chapter 10: p. 261). *OLG* involved a deeper exploration of difficulties that he had dimly recognized earlier, especially the distinction between the civil and the penal branches of jurisprudence and individuation (What constitutes a single law?). The outcome was a dense, but incisive work, which includes original ideas on the logic of the will, a precursor of modern deontic logic.

Bentham elaborated his conception of law in terms later made familiar by John Austin: commands backed by threats made by a sovereign who is subject to a habit of obedience. Yet Bentham's ideas were subtly different. Bentham allowed for limited and divisible sovereignty, whereas Austin did not. The habit of obedience might be partial. Commands, such as judicial orders, need not be general; some laws can be backed by moral or religious sanctions, some laws by rewards. The idea of command has a more complex and limited role in Bentham's theory.

Burns, Hart, and others have explored aspects of Bentham's jurisprudence in detail, including universal censorial jurisprudence; legal positivism and sovereignty; and his analysis of fundamental legal concepts, such as rights and obligations. Less abstract and less well known, but more extensive, are his theoretical writings on codification, adjective law (evidence and procedure), judicial organization, civil law, criminal law, indirect legislation, international law, and many other topics, whose importance is often underestimated. For example, Bentham's writings on evidence represent the most original and wide-ranging contribution to evidence theory in the Anglo-American tradition.

Codification and the Pannomion

From the early 1780s, Bentham's main aspiration was to produce a complete body of laws – a pannomion – to

rationalize and systematize English law and, indeed, any legal system. At first he thought that the main weaknesses of English law were lack of organization, incompleteness, and inaccessibility, linked to the prejudice that legislation was an inferior form of law to common law – defects that might be remedied by a comprehensive Digest. By 1782, he was convinced of the necessity for a systematic structure of codes based on utility and satisfying the tests of coherence, completeness, and comprehensibility. The pannomion encompassed integrated codes on civil, penal, procedural, and constitutional law, backed by detailed legislation on specific topics.

He started with penal law, but was diverted by theoretical concerns into 'the metaphysical maze' of *OLG*. By the late 1780s, he had completed important work on the general theory of law and legislation, but no actual code. Though codification remained his long-term aim, he only returned to the work of actually preparing codes much later. Starting in 1811 he offered his services as a codifier, first for several jurisdictions in the United States, then for Russia, Poland, and Geneva, and latterly for Spain, Portugal, Tripoli, and various Latin American countries. He now prepared some important general works on codification and started drafting several codes. His ideas excited considerable interest, but did not lead to the adoption of a single code. In 1830, he published the first volume of his magisterial *Constitutional Code* (1983). This, together with a procedure code, was only completed after his death by a former amanuensis, Richard Doane. Shortly before his death, Bentham was still 'codifying like any dragon.' He believed strongly that a code should be the product of a single mind, but his failure to complete a single draft reinforced the view that the pannomion was impracticable.

Constitutional Law and Democratic Theory

Bentham was not an instinctive democrat. When young, he was mainly concerned with how legislators should govern. He was prepared to deal with aristocrats, enlightened despots, revolutionaries, and democrats in promoting his ideas. His constitutional theory was a late development. The timing and reasons for his 'conversion to democracy' have been much debated. He was sympathetic to democratic ideas at the start of the French Revolution, but he only became involved in the movement for parliamentary reform after 1809, stimulated by his experience of general resistance and indifference to reform, especially the panopticon. Bentham firmly located sovereignty in the people. He recognized the problem of the tyranny of the majority, but he never satisfactorily solved it, perhaps because of his virulent antipathy to talk of nonlegal rights.

His elaborate constitutional design is based on three axioms: maximization of the happiness of all as the proper end of government; the maximization of the self-interest of the governors as the actual end of government in every political community; and the harmonization of the interests of the rulers and the ruled. His scheme involves vesting real and sustained power in the sovereign people to locate, monitor, and dislocate officials through a system of securities against misrule, especially publicity.

Several of the constitutional writings have only recently become available. The main elements in his code were 'expense minimized, aptitude maximized,' universal manhood suffrage (subject to a literacy test), secret ballots, frequent elections, a unicameral legislature, limited judicial power, accountability and transparency, and a power of recall of office holders, including the military, vested in the sovereign people. He supported ideas backed by other radical reformers of the time. In principle, he favored votes for women, but considered it inexpedient to press for this. Bentham conceived of a constitutional code as a logical and engineered product of a single mind, based on articulated principles, and designed to provide popular control over misrule, patronage, and other forms of corruption.

Bentham and Social Science

Bentham did not draw sharp distinctions between jurisprudence, psychology, political economy, and other fields that have since become semiautonomous social sciences. Utilitarianism requires a concern for social facts. Legislation is the social science. To make calculations the legislator needs reliable information about the existing situation, the likely consequences of a given course of action, and causal relations. He emphasized 'the statistic function' of government; his stepbrother, Charles Abbott, played a leading role in the first population census (Population Bill, 1800); and Bentham himself tirelessly argued for better social data, especially regarding the Poor Laws. This Benthamite enthusiasm was satirized in Charles Dickens's *Hard Times* in Mr Gradgrind, who believed that 'Facts alone are wanted in life.' Bentham believed no such thing. Utility was his guiding principle and he had a sophisticated awareness of the complexities of concepts such as 'fact' and 'causation.' To his credit, he was among those who first recognized and campaigned for the systematic collection of reliable social data as a necessary, but not a sufficient, condition for policy making and legislation.

On 'the art and science of political economy,' Bentham was a follower of Adam Smith, but criticized his defense of usury laws, and on some issues differed from him in either being more averse or more amenable to interventionism. Bentham saw the main role of government as promoting abundance indirectly through ensuring security, the basic presumption being against government involvement in economic affairs 'without some special reason.' But his proposals included provision for many areas later associated with the welfare state, such as public health, education, and the relief of indigence. He argued for the emancipation of colonies both on economic and constitutional grounds and, rather than being a doctrinaire supporter of *laissez faire*, consistently applied cost-benefit analysis to particular issues. Bentham had some impact on the economic writings of James Mill, John Stuart Mill (*see* Mill, John Stuart (1806–73)), David Ricardo, and later W.S. Jevons, Alfred Marshall, and F.Y. Edgeworth (*see* Edgeworth, Francis Ysidro (1845–1926)). There is a useful, but incomplete, edition of Bentham's economic writings (1952–1954).

One cannot enter into detail here about Bentham's psychology, which is regarded by some as his Achilles heel, nor to his extensive and detailed writings on education, poor law, social administration, and other aspects of social policy. There are some interesting affinities with Marx's (*see* Marx, Karl (1818–83)) ideas, for example, the clash between the interests of the few

and the many (though with less emphasis on social class), interest-begotten prejudice, and demystification. But Marx, like Foucault, criticized Bentham without having studied him carefully. Marx treated him as the epitome of 'commonplace bourgeois intelligence.' Foucault interpreted the Panopticon as a symbol of repressive authoritarian control, ignoring the fact that Bentham's concern with transparency applied to those with power as well as those subject to it. Both images are, at best, half-truths. Bentham was also a pioneer in the study of bureaucracy. His standing as a social theorist is ripe for reappraisal.

Influence

Bentham first gained recognition through the efforts of a Genevan, Etienne Dumont (1759–1829), who between 1802 and 1828 produced five elegant French 'recensions' from articles and printed texts. These were more lucid, succinct, and diplomatic than the originals. Some were translated into several languages, including English. The first, *Traité de legislation civile et penale* (1802), made Bentham's reputation in Europe, whence it spread to Latin America and eventually back to Britain.

In the late nineteenth century, Bentham was hailed as the most influential reformer in English history. Subsequently, there has been a continuing debate about the relationship between his ideas and particular reforms. Bentham had both committed disciples and more pragmatic followers who became influential, including Romilly, Brougham, Chadwick, James Mill, and John Stuart Mill; his ideas contributed to the climate of reform in the nineteenth century both in Britain and internationally; many changes, for example, in the Anglo-American law of evidence, moved in directions he had advocated, but in a more piecemeal fashion than he would have approved. He hated jargon, but coined neologisms. Some – codify, maximize, international – have become part of the language. Others, fortunately, have not. Many of his proposals, for instance on codification, have not yet been implemented. How far responsibility for specific changes should be attributed to him or his followers remains controversial.

Bentham Studies

The Bentham Project was begun in 1959 with the objective of producing a definitive edition of Bentham's *Collected Works* (*CW*) in 68–70 volumes. Progress was slow in the early years mainly because of shortage of funds, but also because of the extent of Bentham's articles (more than 70 000 pages) and the extraordinary editorial difficulties. By 2000, 20 substantial volumes had been published and considerable editorial work had been done on others. Between 2000 and 2014 ten further substantial volumes were published with work progressing on the preparation of several more. Since September 2010, the process of initial transcription of hitherto unedited articles has been greatly accelerated by the Bentham Papers Transcription Initiative (generally known as 'Transcribe Bentham'). Using modern technology and employing volunteers, who are recruited internationally and supervised by members of the Bentham Project, almost 10 000 manuscript pages had been transcribed in digital form by mid-2014 and were in course of preparation for an open-source Consolidated Bentham Papers Repository. This will make the bulk of the hitherto unpublished documents available on line as reliable texts before final editing for publication. Transcribe Bentham won an Award of Distinction in the Digital Communities category of the Prix Ars Electronica 2011. Previous holders include *Wikipedia* and *Wikileaks*. This combination of popular participation, new technology, open access, and prestigious recognition would surely have pleased Mr Bentham.

In addition to its main task of producing *The CW*, the Bentham Project has stimulated a range of ancillary activities: the journal *Utilitas* (formerly *The Bentham Newsletter*), the International Society for Utilitarian Studies, conferences, courses, a large and proliferating secondary literature, a growing international community of Bentham scholars, especially in France, Italy, China, and the United States, and some more frivolous/frolicsome activities all of which can be accessed by the Project's very extensive web site. The main outlines of Bentham's life and ideas are well known, and there have been some important specialist studies. In recent years, much more has become available about his detailed views on many topics (including sex, religion, freedom of speech, the Poor Laws, logic and language, fallacies, indirect legislation, and critical jurisprudence). Moreover, recent volumes in *The CW* and the hitherto unpublished articles contain second thoughts, refinements, and new departures that are likely to confirm the view that Bentham was less doctrinaire, and more subtle, original, and genuinely radical than has been traditionally supposed. Revisionism in Bentham studies is now well under way.

Questions arise about his contemporary 'significance.' It is anachronistic to apply early nineteenth-century ideas directly to twenty-first-century issues. Yet, Bentham's views are still relevant to topics as varied as human rights, sovereignty, constitutional reform, freedom of the press, sex, penal policy, torture, corruption, patronage, transparency, accountability, freedom of information, political rhetoric, the legal profession, access to justice, inheritance, free markets, globalization, and 'the farther uses of the dead to the living.' On these and many other issues he is still worth consulting, not least because he often takes provocatively radical positions. As Herbert Hart (*see* Hart, Herbert Lionel Adolphus (1907–92)) remarked, "where Bentham fails to persuade, he still forces us to think" (Hart, 1982: p. 39).

Abstract

The article outlines and reflects on the current state of scientific knowledge of bereavement. Bereavement reactions and associated health consequences are described, and the factors influencing vulnerability and resilience are summarized. We explore ways of coping and links to (mal)adjustment. We outline the current understanding of complicated grief and the effectiveness of psychological interventions. Theoretical developments, particularly those relating to grief complications, are considered. The bereavement research area is rapidly growing and evolving. Many firmly held views have been put to test and sometimes discarded. Therefore, throughout the article, we try to pinpoint key, sometimes controversial, issues and identify directions for future research.

Bereavement, Grief, and Mourning

The Latin derivations of the three closely related basic terms bereavement, grief, and mourning help pinpoint the overlap and differences between them, in addition to suggesting continuity in usage across the centuries. The term 'bereavement' comes from the Latin word *rumpere* (to break, to carry, or tear away). It refers to the objective situation of a person who has recently suffered the loss of a significant person through death. Some types of bereavement such as the loss of a close family member (child, spouse, or parent) have received more scientific attention than others (siblings, grandparents/children). There is room for expansion of research on other meaningful relationships too, including those that sometimes involve secrecy and private suffering (e.g., abortions, death of an ex-marital partner).

'Grief' is derived from the Latin word *gravare* (to weigh down). It refers to the emotional experience of psychological, cognitive/behavioral, social, and physiological reactions to one's loss; it is considered to be a complex emotional syndrome (see Table 1), and it is often regarded as the price we pay for love (thus linking the phenomenon to bonding and attachment to others; see Parkes, 2006). However, it is important to note that not all of these reactions are evident in any particular case and that considerable variation may occur across time and place.

'Mourning' is derived from the Latin word *memor* (mindful). It denotes actions and manners expressive of grief that are shaped by social and cultural practices and expectations that can differ greatly (e.g., the funeral as celebration of life vs as expression of pain; wearing of white vs black to funerals; spreading vs keeping of ashes; an open vs closed casket; removing vs cultivating reminders in one's living context). More research is needed to examine precisely how mourning customs (such as the rituals illustrated above) impact on grief (and vice versa).

The Impact of Bereavement

Although bereavement is associated with detrimental health consequences, it is important to emphasize that it is a normal, natural human experience, one that most people manage to come to terms with over the course of time and without the aid of professional intervention for their grief reactions. Indeed, it is a life event that, sooner or later, affects nearly everyone. Although comparatively rare in childhood, among children

below 18 years, approximately 3–4% can be expected to experience the death of a parent (in Western societies). By contrast, among elderly populations, approximately 45% of women and 15% of men over 65 years can expect to become widowed.

Bereavement is associated with a period of intense suffering for many people and with an increased risk of suffering mental and physical health problems. Adjustment is not confined to the calendar year that is commonly talked of as the expected duration of intense grief; sometimes it can take years. For the most part, researchers have abandoned the use of the word 'recovery' to describe the course of adaptation, acknowledging the experience of many bereaved persons that "one does not get over it, in time one gets used to it." There are substantial variations between individuals and across cultures not only in duration, but also in intensity of reactions. Some people show great resilience in response to loss. For others, typically a minority of bereaved persons, health consequences are extreme and lasting.

Examination of Phenomena and Manifestations Associated with Bereavement

Many questions have arisen and been given scientific attention regarding the links between bereavement and ill-health, for example: Is grief a disease? When might grief make you ill? Some persons develop nongrief-related mental and/or physical health difficulties, and some succumb to complications in the grieving process itself: Who suffers from what and why? Why do some have extreme and lasting effects, while others do not? We begin by addressing the most extreme health consequence, frequently posed as the question: Is there such a phenomenon as the 'broken heart'? Is it myth or reality?

The Mortality of Bereavement

There is considerable evidence that bereavement is associated with an increased risk of mortality from many causes, including suicide. Well-controlled studies now support the conclusion that the heightened risk of dying is attributable in large part to the so-called 'broken heart' phenomenon, if we understand this to imply psychological distress due to the loss, such as loneliness, and secondary consequences of it, such as changes in social ties, living arrangements, eating habits, and economic support. While most research has focused on heightened risk among widows and widowers, recently, it has extended to systematic investigation of mortality following the death of a child. For example, Espinosa and Evans (2013) reported increased risk of mothers dying after their child's death, with indications that the excess risk was concentrated in the first 2 years of bereavement. However, while the myth of the broken heart seems to be confirmed, it is important to emphasize that the investigations also show that in terms of absolute numbers, few people can be expected to succumb to this drastic outcome of losing a loved person; it is a rare occurrence.

The Range of Physical and Psychological Health Outcomes

Given the variety of reactions covered in **Table 1**, it is perhaps not surprising that bereavement is associated with a wide range of physical and psychological ailments and illnesses. Physical health problems are more frequently found among the bereaved than among matched nonbereaved control persons. The former also have higher rates of disability, medication use, and hospitalization than their nonbereaved counterparts. Widowed people consult with their physicians more often, most likely due to symptoms of anxiety and tension, but results of research also suggest that many with intense grief fail to seek medical help when they need to.

Studies have also confirmed elevated rates of psychological symptoms and ill-health, for example, of suicidal ideation, loneliness, insomnia, anxiety, depression, somatic symptoms, and social dysfunction. For a few people, depression or anxiety can reach levels that are of clinical importance. To indicate prevalence: According to some estimates, 25–45% of bereaved people have mild levels of depressive symptoms, while 10–20% reach clinical levels (Stroebe et al., 2007). In some cases, particularly following horrific death circumstances, the bereaved may develop posttraumatic stress disorder.

Recent research has attested to the need for differentiation regarding the range of health consequences. For example, in the past, a generic depression measure was frequently used instead of a specific grief one as an index of the impact of bereavement on mental health. Now it is recognized that grief and depression may, for example, represent distinct, though related, clusters of reactions to bereavement. They may be associated with different risk factors and difficulties and need separate investigation. Nevertheless, similarities have been emphasized. In an influential review, Zisook and Kendler (2007) concluded "The prevailing evidence more strongly supports similarities than differences between Bereavement Related Depression and Major Depression" (p. 779). Another issue concerns the scope of reactions from the typically negative ones listed, to more positive aspects. To illustrate, it is still a matter for consideration where such positive phenomena as personal growth fit in, since research on traumatic losses (particularly) has expanded the understanding of people's remarkable, not uncommon, resilience to enormous losses.

In some cases, the grieving process itself can become disturbed or complicated. Complicated grief (CG) has been variously defined, but most theorists understand it as a form of grief characterized by persistent, intense longing and yearning for the deceased (separation distress), intrusive thoughts or images, emotional numbness, anger or guilt related to the loss, a sense of emptiness, and reactivity in response to cues. At the same time, persons with CG often avoid people and places they associate with the loss, because of the intense distress those reminders evoke. Thus, CG tends to involve the oscillation between anxious preoccupation with and an avoidance of memories of the deceased. In addition, complicated grievers commonly have difficulty in redefining themselves (Mancini and Bonanno, 2006), and often experience difficulties in forming satisfying new relationships or engaging in potentially rewarding activities. The scenario of an initially absent grief reaction followed by a delayed response also seems possible, although empirical evidence on this phenomenon is scarce.

Estimates of the occurrence of CG vary widely, with some reporting 9% of a bereaved adult population and others 20%. In a study of parents who had lost a child through suicide or accident 18 months previously, Dyregrov et al. (2003) reported that as many as 78% scored above a suggested cut-off level on criteria for CG reactions – raising the question whether this

cut-off point is a good marker of CG or whether the norm scores for parents need to be reset (intense grief may not necessarily reflect 'complications').

In recent years, conceptualization and understanding of CG have been strongly channeled by the new Diagnostic and Statistical Manual of Psychiatric Disorders (DSM-5) of the American Psychiatric Association. We return to this below.

Risk and Protective Factors

The term 'risk factor' signifies the situational, intrapersonal, and interpersonal characteristics associated with increased vulnerability associated with the range of bereavement outcomes. Protective factors are those that promote resilience and lower the risk of adverse health consequences.

The situation and circumstances of death contribute to adjustment in complex ways. For example, the broader circumstances of death, including the cause and caregiver strain, must be taken into account. Also, combinations of situational factors (with other types, such as personality factors) can jointly account for the impact on adjustment. While some conclude that sudden unexpected death leads to worse bereavement consequences, others have found that caring for a terminally ill spouse can increase difficulties subsequent to death. Characteristics of the bereaved person or of the predeath relationship with the deceased also play a part. For example, research on attachment has strongly suggested that the quality and nature of the lost relationship is critical to outcome. Childhood loss of a parent has various long-term effects, but importantly, evidence suggests that the adequacy of the remaining parental care after the death of one parent and the resilience of the child him/herself are more powerful predictors of later adjustment than the loss of the parent per se.

Regarding interpersonal factors, a lot has been written over the years about the importance of social support; yet this has now been identified as a general risk factor, i.e., one that affects the health and well-being of nonbereaved to the same extent as bereaved persons. This suggests that others cannot easily take the place of the deceased, or make up for the loneliness following the death. More recently, finer-grained interpersonal processes have been researched and uniquely, intergenerational relationships were subjected to closer inspection. Carr and Boerner (2013) examined the extent to which adaptation to late-life widowhood was not only conditional upon qualities of the late marriage (positive and negative interactions, dependence), but also with parent–child relations in terms of support, criticism, and dependence. Importantly, it was found that widowed persons report significantly less criticism from and more dependence upon children than married controls. Furthermore, effects were conditional upon characteristics of the late marriage: among the bereaved, marital warmth is associated with high levels of support from children post-loss, whereas marital strains were associated with less emotional support from and dependence on children. Widow(er)s who were highly dependent on their late spouse reported lower levels of criticism from children. The importance of including interpersonal variables in risk factor research becomes evident. This extends to interpersonal processes in coping, which have been largely neglected.

Ways of going about dealing with bereavement, referred to as coping strategies or processes (including the interpersonal aspects just mentioned), can impede or facilitate adjustment, and as such can be considered risk factors. Indeed, and unlike many other risk factors, coping is a particularly important factor, because it can potentially be changed (e.g., amenable to interventions). The concept covers many dimensions. Doing one's 'grief work,' for example, used to be considered focal in coming to terms with loss, but more recent research has shown that people who do not work through their grief frequently recover as well as those who do. It was also widely believed that adaptive grieving involved 'letting go' of the deceased. Nevertheless, research over the last decade has shown a potentially healthy role of 'continuing bonds,' although the conditions under which continuing bonds are helpful or not still need to be established. Continuing bonds can reflect a lack of acceptance of the death of the loved one and an effort to maintain a concrete tie, rather than a more internalized, symbolic connection reflecting relinquishment and acceptance of the physical absence of the deceased. There are also considerable cultural differences in their meaning and influence.

So what additional directions should risk factor research take? Many potential risk factors have been underresearched, which is critical, particularly because it creates difficulties for scientists to develop valid screening instruments for use by practitioners. In this respect, studies of multiple risk factors and the interaction between such factors is advisable, rather than focusing (as in earlier studies) on single factors. It is important to establish the relative and the joint impact of risk factors. Finer-grained examinations of maladaptive (interpersonal) coping processes is another important approach that is already gaining momentum, as is the study of positive and negative cognitions and the regulation of emotion in grieving. Theory-guided research along these lines is essential. Finally, further investigation of the ways that risk factors relate to the different health outcomes described above is in order: Why does one bereaved person suffer complications in the grieving process, while another falls physically ill?

CG: Intervention and Diagnosis

We have already indicated that, for a minority of bereaved persons, grieving can take a difficult course, perhaps best summarized as a 'derailing' of the normal, if painful, process of adapting to the loss of a significant person. Given that there are complications, research also needs to address questions about the advisability and effectiveness of intervention. Linked to this are questions about the mental health status of bereaved persons who encounter difficulties in coping with their loss: should these bereaved persons be diagnosed with a mental illness?

Intervention Efficacy

Should intervention be recommended and if so, who benefits from it? More specific research questions include establishing the relative effectiveness of different types of intervention and exploring which type is effective for a particular mental and/or physical health difficulty. In fact, most research has investigated psychological, not medical or pharmacological, interventions, so we focus on the former type of treatment. It is also important

to note that adequate scientific investigation involves the use of randomized control trials (RCTs) for prevention or treatment. To establish efficacy, it is not enough to demonstrate that bereaved persons are satisfied with an intervention program: it needs to be shown that bereaved persons who are assigned to an intervention condition adjust to their loss relatively better than those not receiving treatment.

An approach that has frequently been adopted by bereavement researchers to try to establish who in general benefits from intervention has been to divide the programs into primary, secondary, and tertiary interventions. Primary interventions are those in which (professional) help is available to all bereaved persons, irrespective of whether intervention is indicated. Secondary interventions are designed for those who, through screening or assessment, can be regarded as more vulnerable to the adverse consequences of bereavement. Tertiary interventions refer to programs that provide therapy for CG, grief-related depression, or posttraumatic disorders, which are usually evident longer after bereavement (since pathological processes usually take longer to develop). Conclusions reached have been reasonably unanimous: there is little evidence that all bereaved people will benefit from counseling or therapy. Primary prevention can, however, be helpful when the initiative to get help is left to the bereaved person (indicating need). Secondary preventive interventions for risk groups seem to be an important provision, but as noted above, improvement in risk factor assessment is essential both for better and lasting results of interventions and for the adequate assessment of efficacy.

With regard to tertiary interventions, a wide variety of treatments for grief complications, now including remote modality ones, are available. Systematic comparisons of the relative effectiveness of different therapeutic approaches are still needed to understand what is most effective for whom, but there is evidence that tertiary interventions in general are effective. Wittouck et al. (2013) have reviewed studies investigating the short- and long-term effects of both preventive and treatment interventions specifically for CG. Results of their systematic analyses of the pattern of results of the available RCTs indicate that treatment interventions can effectively reduce CG symptoms. This indication of the efficacy of professional treatment for CG brings us to the related question about the diagnostic status of CG.

Diagnostic Status

Are (severe) complications associated with grief to be considered a mental disorder included in manuals of mental disorders? There has been considerable discussion, and opinions vary greatly regarding the definition and diagnosis of grief complications (cf Stroebe et al., 2013). In the new edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5; APA, 2013), CG, termed persistent complex bereavement disorder (PCBD), is not listed among established disorders but among conditions requiring further research investigation. (While the focus was recently on the DSM-5 (particularly in the U.S.A.), the ICD-11 is currently being drafted and is due for publication in 2015. The ICD system is a core instrument of the WHO, which is in its constitution and is ratified by all the WHO member states.) A further change in the DSM-5 since the previous edition has been the removal of the exclusion of bereavement in the first 2 months from the criteria for the diagnosis of major depressive disorder (MDD). Although the article dictates caution in making a diagnosis of MDD for a bereaved person, concerns remain that in practice, the removal of this exclusion criterion may lead to overdiagnosis of recently bereaved persons as having MDD; early on, they may very well reach the levels of symptomatology defined in the diagnostic criteria for MDD.

An additional concern, given the DSM-5 developments outlined above, is the potential neglect of subtypes of CG, described in classic sources (particularly the clinical literature). Chronic grief, which is similar to PCBD (and as such covered in the DSM-5 to some extent), is characterized by the long-lasting presence of symptoms associated with intense grief. Delayed or inhibited grief have been taken to occur in cases where there is little or no sign of grieving early on in bereavement, but rather, at a later time (clearly, pathology is not always indicated by early lack of symptoms). Absent grief has been understood to be problematic if the person manifests other symptoms, atypical of grief. However, the existence and impact of delayed, inhibited, and absent grief subtypes is currently debated; more empirical research is needed.

Theoretical Understanding

Theoretical approaches to bereavement provide explanations for phenomena and manifestations of grief and grieving. For example, some provide insights into mal/adaptive coping mechanisms, which are potentially useful for guiding research, and ultimately, for applied use in helping the bereaved. Theories vary widely with regard to basic principles, levels of analysis, and degree of specificity. They also range from application to bereavement of general psychological theories such as psychoanalytic and attachment theories or theories of loss and trauma, to bereavement-specific models of coping.

Much theorizing in the bereavement field has been influenced by Freud's (1917) paper 'Mourning and Melancholia.' According to this psychoanalytic approach, when a loved one dies, the bereaved person is faced with the struggle to sever ties and detach the energy invested in the deceased person. The psychological function of grief is to free the person from the ties to the deceased, achieving a gradual detachment by means of the process of grief work. Grief work remained a central concept not only in subsequent theories but also in principles of counseling and therapy. It denotes a cognitive process of going over events that occurred before and at the time of death and focusing on memories and working toward detachment from the deceased. According to Freud, a major cause of pathological grief was the existence of ambivalence in the relationship with the deceased preventing the normal transfer of libido (energy) from that person to a new object.

The notion of grief work has been one of the most persistent features of psychoanalytic theory to influence subsequent research and thinking about coping with bereavement. While its theoretical interpretation is different, it has been incorporated in the major contribution of Bowlby, in his attachment theory (e.g., Bowlby, 1980). Bowlby focused on the biological rather than the psychological origins of grief. According to his

approach, the biological function is to regain proximity to the attachment figure, separation from which has caused anxiety. In the case of permanent loss, regaining proximity is not possible; the response is dysfunctional because reunion cannot be achieved. But an active working through of the loss still needs to be done, as it is an essential part of grief and grieving. The focus on working through grief led Bowlby to formulate phases or stages of grieving (shock, numbness and denial, yearning and protest, despair, and gradual recovery). However, there has been a move away from a phased approach, particularly in view of the evidence that grief and grieving do not follow a predictable, sequential order from initial high distress to return to normal (although it is important to remember that the phases were initially conceptualized as descriptive, i.e., indicating regularities, rather than being prescriptive). One major shift was brought about by Worden's identification of tasks rather than phases of grief (e.g., Worden, 2009), in terms of acceptance of the reality of loss, processing the pain, adjusting to a world without the deceased, and retaining connection with the deceased while embarking on a new life. Worden's tasks have provided clinicians with a 'tool' to help clients work through their grief. A further major development has been Bonanno and colleagues' (e.g., Bonanno et al., 2008) identification of trajectories of grief. Their research showed that there are qualitatively distinct pathways across the months following the loss of a loved one, supporting the conclusion that the grieving process cannot be well described in terms of a single set of stages or tasks. Bonanno's research suggested that resilience is actually common and that delayed grief is rare.

In other respects, attachment theory has also remained enormously influential in contemporary bereavement research. Early childhood experiences with attachment figures are still considered critical. These experiences are understood in terms of the development of either secure or insecure bonding with the caregiver, and this emerging style of attachment has a lasting influence on later relationships. To illustrate, frequent separation from attachment figures in childhood can lead to anxious attachment in later relationships, which is associated with chronic grief. Mikulincer and Shaver (e.g., 2013) have conducted sophisticated empirical research, confirming the importance of attachment security in the prediction of adjustment to bereavement and providing a fine-grained understanding of many associated phenomena.

Diverse trauma and stress theories have influenced the understanding of the phenomena and manifestations of bereavement. One major line of work is represented by the work of Horowitz and colleagues (e.g., Horowitz, 1986), applicable to traumatic events in general. A basic assumption of this approach is that stressful life events (SLEs) play an important role in the etiology of various somatic and mental disorders. A further line of research derived from the related field of trauma was that of Janoff-Bulman (1992), particularly through identification of shattered beliefs, which need to be rebuilt. This has been expanded to the study of 'meaning making' particularly by Niemeyer and collaborators (e.g., Neimeyer, 2001), giving centrality to the need for 'making sense' and 'finding meaning' after the loss of a loved person. A basic idea is that the reconstruction of meaning about the self and the world is critical to adjustment. Difficulties in establishing the role of meaning making in adjustment remain (e.g., studies have not always succeeded in separating the process from the outcome, beliefs from adjustment, or establishing the direction of causality among these factors). Others have distinguished two components of meaning-making. Davis et al. (1998) identified two distinct processes, making sense of the loss and finding benefit, which entail distinguishable psychological concerns for the bereaved person, with, for example, the former diminishing in importance in time, while the latter growing stronger as time goes on.

Stress theorizing received independent impetus through the work of Lazarus and Folkman (1984), who provided detailed analyses of coping processes, through which SLEs may precipitate poor physical or mental health outcomes. A major premise of their cognitive stress theory is that the intensity of stress created by an SLE depends on the extent to which the perceived demands of the situation tax or exceed an individual's coping resources, given that failure to cope leads to negative outcomes. Recently, research has identified neurophysiological mechanisms linking stress with various detrimental consequences to the immune, gastrointestinal, and cardiovascular systems (O'Connor, 2013). Folkman (2001) applied cognitive stress theory specifically to the stressor of bereavement, significantly extending the perspective to include positive emotions/appraisals as a component in coping with bereavement. Drawing partly on this theoretical approach, Stroebe and Schut (1999) developed their dual process model (DPM), a bereavement-specific coping model, to try to capture the complexity, diversity, or idiosyncratic nature of grieving. They postulated two types of stressor, the first called loss orientation, which relates to the deceased person (e.g., ruminating about the death), and the second restoration orientation, which has to do with secondary stressors that come about indirectly but as a consequence of the death (e.g., dealing with new financial concerns). Rather than assuming phases or tasks, the DPM includes an emotion regulation process, labeled oscillation. Adaptive coping entails oscillation between the two types of stressor and 'time out,' given the necessity to rest from the arduous process of dealing with the loss.

Conclusions

Loss of a loved one can cause deep suffering and the risk of mental and physical health detriments, but it is important to remember that grief is a normal, natural response to bereavement. Most reactions are not complicated and for most persons, family and friends, religious and community groups, and various societal resources will provide the necessary support. Professional psychological intervention is generally neither justified nor effective for uncomplicated forms of grief.

Although advancements across all the areas of research reviewed above have been evident in recent years, improvement in the design of research projects is often indicated, for example, in the design of intervention programs and for strict assessment of their relative effectiveness, following evidence-based criteria. Furthermore, gaps in knowledge still remain. So what directions should future research take? Both micro- and macrolevel extensions can usefully be pursued. At microlevel, one line of research that is currently expanding is fine-grained cognitive/emotional (regulatory) process analyses,

including physiological measurement. Laboratory techniques are beginning to answer questions about distinctions between adaptive grief work and maladaptive rumination and to link these to confrontation versus avoidance processes.

At macrolevel, more research is needed that not only focuses on bereaved individuals, but also on families, organizations, and cultural groups, to investigate broader changes that may be triggered by a loss. Inclusion of underacknowledged, disenfranchised groups within this wider scope seems essential and many examples come to mind, such as those with learning difficulties, expartners, nursing home and home care staff's grief for their patients. Finally, much is still to be learned about – and to be gained scientifically – by extending consideration to losses without physical death, such as organ donation, euthanasia, dementia, or irreversible coma.

Bereavement and Complicated Grief across the Lifespan

Abstract

Loss can be seen as a normative life event; nevertheless for most individuals, the experience of the loss of a loved one is extremely stressful. The grief reaction is universal but shaped by cultural norms and individual expectations; grief may also become a serious health problem. The aim of this article is to review the consequences of grief as well as explanations and treatment of complicated grief disorder. Five areas are identified to be of importance to clinicians and researchers: (1) grief reactions, (2) models of grief, (3) bereavement across the life span, (4) diagnostic criteria, and (5) treatment for complicated grief.

Introduction

Bereavement after a loss is a normative but threatening life event that can lead to serious consequences, such as anxiety, sleep disorders, problems to adapt, depression, and even death. A loss of a person is often shared among many individuals who have developed different bonds with the deceased person. Henceforth, grief is often a shared experience but bereavement is rarely the same for different individuals. Besides individual coping with loss, there are cultural aspects of grief and bereavement that also have to be accounted for. Evidence exists that grief can become a disorder, similar to other emotional disturbances such as anxiety disorders or disruptive aggression (Shear et al., 2011). Therefore, the question of therapeutic intervention must be seen in this context.

In this article, the focus will be on coping with loss across the life span, the question how grief can be conceptualized as a normal reaction to loss and on risk factors for developing a loss-related disorder. The proposed diagnostic criteria will be presented in this article.

Grief Responses

Humans share as other social animals the capacity to build long-lasting social relationships. Attachment is perceived as a natural basic need and we are attached to others in various ways, as dependent children and lovers, or because we share the same living circumstances. Following the work of Bowlby (e.g., 1980), the loss of an attachment figure may lead to massive stress, even to death. In a biological sense, grief is the price humans pay for the capacity to form social bonds, groups, and communities. Grief is the individual response to separation distress, which is caused by a genetically provided subcortical network (Panksepp and Watt, 2011) leading to emotional responses such as panic, sadness, and a diminished strive for dopamine-driven activities. Indeed, many bereaved parents expressed their grief in metaphors relating to bodily loss (Znoj, 2004). Following the work of Stroebe and coworkers (Stroebe and Schut, 2001), the intensity of the grief response is more related to the relationship of the deceased person and less to other circumstances of the loss. This corroborates the notion that grief and related disorders are consequences of a breakdown of the bonding system and constitute a specific form of threat.

Models of Grief

A variety of models aim at explaining grief. Phase models of bereavement are still popular by providing a system that is both logical and dynamic. After initial shock and disbelief, the bereaved is assumed to go to further stages of adaptation, namely to realization of the loss and grief work that includes the gradually disengagement from the target person and finally the resumption of emotional life and the capacity to form new intimate relationships. These phases are generally conceptualized as sequences. However, most researchers agree that this view is oversimplified.

Some models focus on coping with losses. The task model (Worden, 1996) suggests four tasks to adjust to bereavement. In contrast to just passively experiencing the loss, it focuses on active coping with the challenges, namely accepting the reality of the loss, experiencing the pain, adjusting to an environment without the deceased person, and finally finding a new understanding with the deceased. Coping models often focus on various coping styles, such as avoidant coping or rumination (e.g., Nolen-Hoeksema and Jackson, 1996) that often lead to elevated depression and higher distress levels later on. In contrast, a problem-oriented coping leads to better adaptation and includes distractive coping, even cognitive avoidance (e.g., Bonanno, 2004). Positive meaning and meaning reconstruction following bereavement have been linked to positive outcomes following loss; the capacity to display positive emotions during bereavement predicts better outcome after the loss of a spouse (Bonanno and Keltner, 1997). Taken together, these results may indicate that too much avoidance as well as too much confrontation is detrimental to adaptation following loss. Stroebe and Schut (1999) proposed the dual-process model that integrates both stress and coping theories as well as psychosocial models, such as the two-track model (Rubin, 1981) addressing both, the biosocial responses to bereavement and the transformation of the attachment that may include a new still ongoing relationship with the deceased person. The integrative dual-process model of grief takes into account the empirical evidence and postulates an oscillation

between loss-oriented coping and restoration-oriented coping. Loss-oriented coping includes positive reappraisal versus rumination, wishful thinking, revisions of personal goals, positive and negative event interpretation, and expressing emotions and mood states such as dysphoria or positive effect toward the deceased. On the other hand, restoration-oriented coping is focused on attending to life changes, doing new things, distracting from grief, and finding new roles and identities.

For stress–response disorders in general, Horowitz' (1978) model of working through a traumatic event posits an oscillation between phases of intrusion and avoidance as necessary process for adaptation. A good fit can be found between the dual-process model (Stroebe and Schut, 1999) and deepened investigation of risk factors as has been shown for cognitive–emotional changes after bereavement (Znoj, 2004). For instance, anger about the circumstances of the death of a loved one could lead to more severe grief, specifically when the death is perceived as unjust, such as in the case of the death of a child. For example, Znoj et al. (2004) investigated bereaved parents and found high correlations of the feeling that fate is unjust and increasing psychopathology. Orth and Maercker (2009) demonstrated that anger, in addition to post-traumatic stress disorder (PTSD) symptoms, leads to further aggravation of symptomatology.

In Western societies, the belief exists that grief should be resolved within 12 months (Wortman and Silver, 1989). Zisook and Schuchter (1986) described persons within the first year of widowhood. While the majority had adapted well after 4 years, some individuals still felt responsible for the loss and reported symptoms like preoccupation with thoughts of the spouse, or had clear visual images; moreover 40% reported elevated levels of depressive symptoms. Overall, the symptoms degraded slowly over time. Obviously, the process of grief lasts longer than usually assumed by the general population. Some of the symptoms clearly have a negative impact on well-being, such as intrusive longing, pain, bouts of crying, and worrying. However, depressive thoughts may also hint toward personal growth and the stimulation of human resilience (e.g., Znoj, 2006).

Loss Experience and Bereavement across the Life Span

Vivid memories, emotional turmoil, high levels of anxiety, and depression are seen as normal reactions to the loss of a beloved person in adults. Information about grief reactions in children or young adults is scarce. Depending on age and developmental stage, a child or young adult will have different concerns. Following Christ et al. (2002), between 3 and 5 years of age, the concept of death is hard to grasp or even absent for most children. Therefore the child will ask about the deceased person as if he or she will come back or is just temporarily unavailable. Magic thinking and fantasy are predominant and the child will experience a great deal of distress when separated from the primary caregiver but eventually accept a competent substitute. Between 6 and 8 years of age, the child begins to understand that death is a universal fact and therefore the parent will not return (Oltjenbruns, 2001). However, the causes and effects are often not well understood, and parents are an important source of emotion regulation and self-esteem. Fear, anger, and aggression, or wishes to be together with the deceased parent can be harmful (e.g., danger of suicide). Between 9 and 11 years, the child becomes slowly independent, the improved logical thinking supports understanding the cause and effect, but even then child needs concrete details (e.g., about illness) to come to a conclusion. Emotion regulation relies on distraction strategies and seeks actively support with peers and relatives. Bereaved adolescents often have a strong sense of the dead parent's presence and accept him or her as a gender role model. In older adolescents between 15 and 17 years of age, grief has adult characteristics with overwhelming sadness and painful memories but usually the duration of intensive grief is shorter than among adults.

In each of these developmental stages, grief can become overwhelming and a source of intense distress. Complicated grief (CG) can be observed in any of these stages and is usually characterized by deterioration of social aspects as well as depression, including regressive states, phobias, loss of emotional and behavioral control, or reduced cognitive ability.

Because the cognitive and emotional apparatus is changing, Oltjenbruns (2001) observed the phenomena of regrief, meaning that at a later developmental stage, the loss can be reexperienced and more intense than before. In this perspective, the loss of a mother with the 4 years of age can have a different but no less powerful impact on a young woman of 17 years of age, when she would need her motherly advice and support to develop her own life in the transition to adulthood.

Silverman and Worden (1992) investigated 125 children from 6 to 17 years of age within 4 months of the death of a parent. After 4 months, the effective response stabilized fairly for most children; however, 74% reported headaches or other somatic problems, one-third had sleeping problems they attributed to their parent's death. Further problems included difficulties concentrating in school, hassling by peers, or uneasiness at the absence of one parent. To remain connected with the deceased parent seemed to be a strong motive for children and youths at least in this study. In sum, "the deceased parent continued to be a real presence for many of the children who carried on a relationship similar to the one prevailing before the death" (Silverman and Worden, 1992: p. 100). Balk and Corr (2001) resumed that the risk of depression following the death of a parent is seven times higher than the norm. In an effort to shed more light on this underinvestigated area, Schwartz (2003) interviewed 39 youngsters between 10 and 22 years of age in the Bern study within 6 months to 5 years after the loss. For more than 50% of these youngsters, the death came sudden, unheralded. Eighteen percent of the bereaved children and youngsters had clinical relevant levels of depression. Avoidance and retreat were closely related to depression ($r = 0.50$, $p < 0.01$), whereas seeking support was negatively related to depression. Although 50% of the bereaved reported to be not religious, almost all wanted their parents to be well-off in Heaven and almost three-fourth uttered the opinion that their deceased parent can hear them, and therefore tried to contact them via praying. Almost half of the bereaved children indicated having vivid dreams and feelings of presence of their deceased parent. One-third even heard their deceased parent as if he or she would still be alive. Level of spirituality and religion were positively correlated with social support, especially by

grandparents ($r = 0.49$, $p < 0.01$), and also with feelings of presence ($r = 0.33$, $p < 0.05$).

In terms of long-term consequences of childhood adversities, Cuijpers et al. (2011) also looked at bereavement in a large population sample in The Netherlands. While childhood adversities in general had very high impact on the disease burden in adulthood, the death of a parent had no effect. This suggests that bereavement in childhood might not necessarily lead to long-term negative consequences. However, this finding needs to be replicated.

Child loss is one of the most challenging losses a person can experience. In the Bern study of parental bereavement, we (e.g., Znoj, 2004, 2012) found extremely high levels of intrusions as measured with the Impact of Event Scale (Maercker and Schützwohl, 1998). Bereaved parents also reported high levels of depression; they often experienced the loss as if they were physically amputated and in physical pain. The loss of a child can be seen as a serious risk factor for prolonged grief.

For elderly people, the loss of a close person is a normative event and especially old age is a time of multiple sequential losses. After Moss and Moss (1986), two-fifth of persons over 60 years of age experienced already the loss of a sibling. Conjugal bereavement, the death of a spouse, is also an important topic and often the bond persists and continues beyond the death. Following Lopata (1996), loneliness is among the most mentioned consequences of widowhood. Most widows and widowers live alone but many acquire new skills and develop in positive ways. The impact of the loss may be less intense than in younger years but the emotional distress and grief decline more slowly among older persons (Moss et al., 2001). Mortality risk is elevated, especially for widowed men (e.g., Verbrugge, 1989). Moreover, a special situation arises when there is a generational violation, especially when a child dies before an elderly parent. In addition to intense emotional distress, such a loss may imply a breakdown of the supportive system and may have serious health consequences. Research is rare, despite the fact that adult children play a major part in the social and emotional world of parents throughout their lifetime (Moss et al., 2001). The death of an old person – on the other hand – is often experienced as a relief (the suffering has ended) and may lower the emotional impact of the loss for close persons.

Diagnostic Criteria for Disordered Grief

Emotional and behavioral consequences of a loss are intensive sadness, anxiety, aggression toward the deceased or persons related to the loss, and, sometimes, dissociative states. In contrast to other traumatic experiences, the experience of a loss is related to the capacity of building lasting bonds to significant others, including parents, spouses, children, and close friends.

Nevertheless, the reaction to loss is structurally similar to traumatic events (Horowitz, 1978) and often results in emotional dysregulation. For most people, grief intensity weakens to a manageable degree within several months. After the most intensive period, grief is still present but the loss becomes gradually integrated and no longer hinders the way of ongoing life. Similarly, most immediate stress reactions following life-threatening events recede over time. Only when stress symptoms exist beyond 4 weeks, a diagnosis PTSD can be given.

Horowitz who provided the first description of the PTSD criteria and symptoms had pointed early to similarities shared by psychotrauma (PTSD) and grief. He and colleagues called this family of failure to adapt to stress the 'stress–response syndromes' (e.g., Horowitz, 1978). This concept is becoming increasingly recognized.

Up to today, grief patients receive a variety of International Classification of Diseases (ICD) or Diagnostic and Statistical Manual of Mental Disorders (DSM) diagnoses, for example, PTSD, depressive, anxiety, adjustment, and personality disorders (Enright and Marwit, 2002). The clinical utility of these labels, however, has to be called into question and mostly they do not describe the difficulties experienced after the loss of a loved one adequately.

The point at which the state of a mourning person becomes a disorder has been debated from many strands. The debate centers on the extent to which complicated or prolonged grief represents a unique pathological entity when contrasted with normal grief, but also with PTSD or major depression. However, consensus is that grief can be complicated, much as wound healing can be complicated (Shear et al., 2011). One easy accessible indicator is to listen to clients or patients. Self-statements like "I fear, I go crazy if I fully realize the death of my loved one" is very specific to CG but not to depression (Boelen et al., 2006).

Diagnostic Criteria for Complicated Grief Disorder

Only recently have Prigerson, Horowitz and other proponents of a separate classification for complicated grief disorder (CGD) reached a consensus on its clinical criteria (Prigerson et al., 2009). The consensus results from a reanalysis of field trial data from the Yale Bereavement Study (317 participants). These participants were interviewed repeatedly at different time points after the loss of a close person. The symptoms of CGD were assessed using an extended rater version of the Inventory of Complicated Grief-Revised (Prigerson et al., 1995). Analyses aimed to derive a set of informative, unbiased symptoms that allow proposing a complete set of 'DSM-style' diagnostic criteria.

The resulting set of diagnostic criteria specifies that a bereaved person with CGD must experience yearning and at least five of nine additional symptoms (**Table 1**). These symptoms must persist for at least 6 months following the loss and must be associated with functional impairment.

Finally, the study showed that individuals given a CGD diagnosis 6–12 months after a death have a 2.4 times higher subsequent risk of mental health and functional impairment than people not diagnosed with CGD.

Treatment of Complicated (Prolonged) Grief Disorder

In the following, current treatment approaches to CGD will be outlined. Shear's approach of treating CGD has become widely recognized (Shear et al., 2005). This approach was essentially informed by the imagined and *in vivo* exposure techniques used for PTSD, including the confrontational technique of 'revisiting' the deceased loved one. With this technique, the therapist asks patients to close their eyes and tell the story of the death.

Table 1 Prolonged grief disorder criteria proposed for inclusion in *Diagnostic* and Statistical Manual of Mental Disorders V (DSM-V) (by the American Psychiatric Association)

1. Event: the person has experienced bereavement, i.e., the loss of a significant other.
2. Separation distress: the bereaved person experiences separation distress most days and to a disabling degree, as manifest by yearning, longing, craving, or pining for, or preoccupation with the deceased person.
3. Additional cognitive, emotional, behavioral symptoms of grief: the bereaved person must have five (or more) of the following symptoms experienced most days and to a disabling degree:
   a. Confusion about one's role in life or diminished sense of self (i.e., feeling that a part of oneself has died)
   b. Difficulty in accepting the loss
   c. Avoidance of reminders of the reality of the loss or avoidance of thoughts, activities, or situations that arouse intense emotions related to the loss
   d. Inability to trust others or feeling alone or detached from others since the loss
   e. Bitterness or anger related to the loss
   f. Difficulty in moving on with life (e.g., making new friends, pursuing interests, feeling life no longer holds the potential for satisfaction or joy)
   g. Numbness (absence of emotion) since the loss
   h. Feeling that life is unfulfilling, empty, meaningless, or unbearable since the loss
   i. Feeling stunned, dazed, or shocked by the loss
4. Timing: diagnosis should not be made until at least 6 months have elapsed since the death.
5. Impairment: the disturbance causes clinically significant impairment in social, occupational, or other important areas of functioning (e.g., domestic responsibilities).
6. Relation to other mental disorders: the disturbance may co-occur with but is not better accounted for by major depressive disorder, generalized anxiety disorder, or post-traumatic stress disorder.

The therapist tape-records the story and periodically asks the patient to report distress levels. The patient is given the tape to listen to at home during the week. Distress related to the loss (e.g., yearning, or fears of losing the deceased forever) is targeted using techniques to promote a sense of connection to the deceased. These include an imagined conversation with the deceased. This technique is complemented by preceding psychoeducation and a subsequent 'restoration of life goals' phase. Shear et al. (2005) compared this treatment to standard interpersonal psychotherapy. The results were much in favor of Shear's CG treatment, so that this treatment approach is now being disseminated and applied around the world.

Boelen et al. (2007) studied a modified form of this treatment and examined different sequences of exposure and cognitive restructuring (CR). Exposure began with the writing of distressing memories and included in sensu exposure during the sessions. CR focused on individual dysfunctional thoughts (e.g., guilt, anger). Doing exposure first, followed by CR, yielded the best results.

Because no other approaches have been shown to be effective aside from those tested in these randomized trials, the Web-based approach for CGD (Wagner et al., 2007) might be of importance. This approach also begins with a technique of self-confrontation similar to that used for PTSD consisting of a written assignment. Patients are asked to write four texts where they describe the circumstances of their bereavement and their thoughts and feelings at that time. The therapist facilitates the nonavoidance of fear related to these memories. The CR is then based on these accounts focusing mostly on the feelings of guilt or responsibility in the death of the loved one. Patients are then asked to write a supportive letter to a friend who finds himself or herself in exactly the same situation. A further intervention consists in establishing rituals or activities to commemorate the deceased. The aim is to give the deceased a place in everyday life, to reorganize priorities, and to see how the patient can consider reconnecting with friends and social life. Within 10 weeks, patients write a total of 10 assignments, to which they receive an individual feedback from the therapist via e-mail within one workday.

Due to the Web-based intervention, the group of patients was highly selective. There were a number of exclusion criteria that were necessary due to the virtual nature of the relationship between patient and therapist. In a randomized controlled trial with a wait-list control condition, the effect sizes were in the range of 1.2–1.5, and 1.2–1.6 for pretreatment to 3-month follow-up. Follow-up measures at 18 months confirmed the stability of these effects (Wagner and Maercker, 2007). Further results confirmed functional change in the five domains of posttraumatic growth (new possibilities, relating to others, appreciation of life, personal strength, spiritual change), but no significant increase in optimism was observed (Wagner et al., 2007).

Overall, evidence shows that good therapeutic success can be achieved with exposure and CR. The efficacy of these two standard modules, also found in therapy for PTSD, will perhaps be enhanced with a third module consisting of social sharing. The sharing of pain with others in an appropriate way seems to be an important issue. Social sharing as treatment goal may also be specifically suited for group treatments of CGD.

Outlook

In PTSD, people typically fail to assimilate their experiences and have prevailing fundamental beliefs and specific experiential readiness. The consequences of PTSD are strong negative emotions and a constant cognitive preoccupation to detect dangerous inconsistencies. In contrast, in CGD the predominant feeling is not threat but loss-related distress. The persisting inconsistency concerns lack of affiliation. A failure to adapt following a major loss of an attachment figure may not only lead to a complicated or prolonged grief disorder but also to other forms of psychopathology such as depression or panic disorder. It is probably of highest importance not only to look at grief-specific symptoms but also to the individual processes of coping. Our own work (e.g., Znoj, 2008) has shown that processes of emotion regulation may lead to completely different outcomes after the loss of a loved one. Grief and the experience of loss and death is part of the human condition, social and cultural aspects shape the individual's response. The question whether we perceive a grief response as part of the social life or whether we focus on individual suffering and

consider the necessity of individual treatment requires careful indication and extensive future developments.

Abstract

Isaiah Berlin (1909–97) was a British philosopher, social and political theorist, essayist, and intellectual. He is most renowned for his work in the history of ideas, a field that he made attractive again for philosophy and the social sciences against the current of analytical philosophy. His major analytical contributions concern the distinction between positive and negative freedom and the problem of value pluralism in modern societies. Upon his death, he was above all venerated for his personality, his conversational art, his brilliant style, his steadfast opposition to totalitarianism and his unflinching commitment to liberalism.

Isaiah Berlin was a British philosopher and an ardent liberal who defended political freedom in modern society against totalitarian temptations of all kinds. He started his academic career as a conventional philosopher preoccupied with logical positivism and language philosophy but soon began to work in the field of the history of ideas. He focused on the enlightenment and developed a keen interest in the thought of the counterenlightenment; he also dealt with romanticism and the Russian thinkers, above all Alexander Herzen. The main thrust of his multiple and voluminous essays is not easy to capture. Berlin never made a serious attempt to systematically elaborate his own approach in the history of ideas. An exception from this might be his narrative 'My intellectual path' (Berlin, 2000: 1–23) in which he laid out the development of his thought. When pressed to display his intellectual agenda, he used to answer laconically: "I am an intellectual taxi: people flag me down and give me destinations and off I go" (Ignatieff, 1998: 7).

A strong aversion to theoretical systems was part and parcel of Berlin's intellectual habitus. He preferred to work from a kind of latent 'systématique' without spelling out its logic. When reconstructing the systematic approach behind his articles, it should thus be clear that we are dealing with an interpretation of Isaiah Berlin's work open for refutation. In my view, there is neither a coherent intellectual system nor one *idée directrice* to be found throughout Berlin's work (though liberty and value pluralism would be possible candidates). Instead, Berlin employs what – with Arthur O. Lovejoy (1942) – might be called an ensemble of unit-ideas, certain core thoughts or elements in the history of philosophical doctrines. We can use this concept of unit-ideas for the reconstruction of Isaiah Berlin's approach to the history of ideas as well as the evolution of this approach: In his social and political philosophy the unit-idea he started from was the rational monism of the Enlightenment. This unit-idea is characterized by a tripartite dogma: (1) in epistemology and ethics there is but one answer to all genuine problems; (2) if found, this answer represents the truth; and (3) all true propositions cannot conflict with one another because there is only one truth.

While Berlin acknowledges the liberating ideals of perfectibility and progress that this notion entails, he is also alert to the danger that when realized recklessly by 'enlightened elites' these very ideals might lead to oppression and totalitarianism instead of a liberal and open society. The antimonist stance Berlin develops from this insight also leads him to his other three unit-ideas: The modern condition is above all characterized by value pluralism, the quest for liberty, and political liberalism. In working out these unit-ideas Berlin draws on Counter-Enlightenment and Romanticist thought as well as the Russian intellectual tradition. Although it remains somewhat uncertain what ultimately holds Berlin's *oeuvre* together, in my view his intellectual agenda can be identified as the attempt to decipher the constellation of values and institutions of modernity, which ensure that liberty is not only paid lip service by governments and states but can be enjoyed by ordinary people in everyday life.

Life and Career

Isaiah Berlin was born on 6 June 1909, in Riga, Latvia, which belonged to the Russian Empire at the time. His father, Mendel Berlin, was a prosperous timber merchant. The family moved to St Petersburg in 1917 where young Isaiah would witness the violence of the Russian Revolution. This early experience made him a stern anticommunist throughout his life. He came to see the 'true freedom' communists promised as a mere pretext for an oppressive rule based on violence and totalitarian ideology. Soon after the return to Riga in 1920, the family decided to emigrate to Britain.

In London, Isaiah Berlin visited St Paul's School and went to Corpus Christi College, Oxford. He studied Greats (philosophy, ancient history, and classical languages) and philosophy, politics, and economics. He entered All Souls upon election to a Prize fellowship and was the first Jew to be nominated. Berlin started a career as a philosopher at Oxford. But after he had given a paper on 'Other Minds' in Cambridge followed by a fierce discussion with the young Ludwig Wittgenstein (who politely dismissed him by saying "Very interesting discussion. Thank you" (Ignatieff, 1998: 95)), he gave up philosophy in favor of the history of ideas.

Oxford turned out to be his *alma mater* for a lifetime. Upon his death, his All Souls colleague William Waldegrave remarked in the *Daily Telegraph*, "if you had asked me to show you what I meant by the ideal of Englishness, I would have taken you to see a Latvian, Jewish, German, Italian mixture of all the cultures

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61160-1

of Europe. I would have taken you to see Isaiah Berlin" (Ignatieff, 1998: 300).

Yet, despite this story of successful integration into a renowned English institution, his social environment would not forget that he was a Jewish-Russian *émigré*. During the Second World War, Berlin worked as a correspondent first in New York City, then in Washington DC in the British Embassy. He was charged with delivering weekly reports from the United States. Due to his brilliance, those reports soon gained notoriety. Prime Minister Churchill wrote to his Foreign Secretary in 1944: "The summaries are certainly well written. I have a feeling that they make the most of everything and present a somewhat perfervid picture of American affairs." Eden commented in his own hand: "I agree. There is perhaps a too generous Oriental flavor" (Ignatieff, 1998: 125).

The years after the war elevated Berlin's prominence to a new level. His reports from Washington had gained him a reputation in Whitehall and the upper society was curious to come to know this young and gifted philosopher from Oxford. The British Broadcasting Corporation invited him to broadcast and Churchill let Berlin review his memoirs. The journal *Foreign Affairs* invited him to contribute and his two articles earned him the reputation of being an expert on Soviet Russia. As a consequence, he was invited to US universities, among them Harvard, Bryn Mawr, and Princeton.

Yet, his worldliness and frivolity – he was afraid to become an intellectual 'chatterbox' – raised the question of his own intellectual agenda. He found it in Russian intellectual history, the history of socialism and Marxism, the Enlightenment and its critics. In 1950, he returned to All Souls with a fellowship and devoted his time exclusively to research. In 1957, he became the Chichelle Professor of Social and Political Theory at Oxford, the same year he had married Aline Halban (née de Gunzbourg) and was knighted. His inaugural lecture in 1958 developed the famous distinction of the 'Two concepts of Liberty.' Berlin resigned his Chair when he was nominated to be the founding President of Wolfson College in 1967. From 1966 to 1971 he served as a visiting Professor of Humanities at the City University of New York. He became the President of the British Academy in 1974 and resigned from this post in 1978. Berlin received numerous prizes – among them the Agnelli, Erasmus, and Lippincott Prizes – for the history of ideas and the Jerusalem prize for defending civil liberties throughout his life. He was awarded with a number of honorary degrees.

In retrospect, Berlin's intellectual identity was the result of a number of different forces, of which three bear special mention: a Russian, British, and Jewish one. The Russian thinkers, above all Herzen and Turgenev, furnished in him the fascination for ideas and the proper moral role of the intellectual. The British environment instilled in him a sober sense of reality and the matter-of-fact mentality of empiricism as well as liberalism and tolerance. His Jewish heritage led him to pursue a moderate Zionism, probably an expression of his own need for belonging. He steadfastly defended this position against the critique of cosmopolitans.

During his lifetime, Isaiah Berlin published just one monograph, his classic on Karl Marx in 1939. Starting in 1978, Henry Hardy, a student of Berlin, set out to publish his other writings. Thanks to Hardy's editorial work, an amazing oeuvre has emerged in recent years comprising 13 books, among them an anthology, 'The Proper Study of Mankind' (Berlin, 1997) and a collection of letters in three volumes (2004, 2009, 2013a). Berlin died on 5 November 1997, in Oxford.

The Early Achievement: Isaiah Berlin's 'Karl Marx'

Berlin, at the time just 30 years old, wrote a remarkable intellectual biography of Karl Marx, which is still in print. The subject was somewhat inopportune at the time because soon after his first book was published, the Second World War broke out. The original manuscript was twice as long. But Berlin was pressed by his publishing house to cut one-half in order to bring the book to the agreed-upon length. The young author rewrote his manuscript more as an intellectual biography than an exegesis of Marx's theory of history, his economic and sociological analysis.

What is the trademark of Berlin's Marx? Three critical insights are decisive: (1) Berlin's empathy for Marx, (2) the problem of historical inevitability, and (3) the role of ideas. Berlin draws a balanced and nuanced picture of Marx's accomplishments and weaknesses. In his first major work, Berlin already exhibits a unique ability to bring historical persons and constellations to life. Berlin's great virtue is precisely his 'empathy for the other.'

It goes without saying that Karl Marx embodies for Berlin the 'other.' The project in this earliest work is to make Marx the adversary look as strong as possible and then demonstrate why he is dangerously wrong.

Marx's historical materialism set out to determine the laws of social development based upon a model of economy and society, the famous 'base' and 'superstructure.' Yet, for Berlin, Marx made much too strong a point in claiming this sort of 'historical inevitability,' the necessary transformation of bourgeois capitalism into proletarian socialism. In Berlin's eyes, the history of mankind is contingent, the development of society open, and the future unpredictable. Socialism may be mankind's future but this is dependent upon the ideas people have, the course of action they take, and critically, the amount of blood they are willing to spill.

The third point pertains to the role of ideas in Marx's theory of history. According to Marx, ideas are ideological illusions. What determines the course of history and society are the iron laws of capitalist production and contradiction. Ironically, Marx's own ideas belie this interpretation, since those ideas made a great deal of world history themselves.

In his struggle with one of the most important thinkers of the nineteenth century, Berlin tapped into problems and questions he would deal with throughout his academic career: the philosophy of history, historical inevitability, progress and perfectibility, the role of ideas. In retrospect, Berlin credited Marx with having contributed three main ideas: "The idea of Marx that was genuinely original was the idea of the influence of technology on culture, that technological change influences culture to a profound degree. (…) The other idea was about big business and what it did. (…) The third idea is that of the class war. Class warfare has been exaggerated, but nevertheless exists as a phenomenon. There is such a thing as conflict between classes" (Berlin and Lukes, 1998: 71).

Two Concepts of Liberty

Berlin's most famous work is the inaugural lecture 'Two Concepts of Liberty' given in 1958 after he had taken the Chair of Social and Political Theory at Oxford. Berlin tries to turn the manifold meanings of this notion into a coherent concept by drawing a distinction between negative and positive freedom. Negative liberty (Berlin used to employ the terms liberty and freedom interchangeably) refers to a private realm of the individual where he or she is free to choose: "By being free in this sense I mean not being interfered with by others. The wider the area of non-interference the wider my freedom" (Berlin, 1969: 123). In particular, political liberty requires a strong frontier between the public and private realm. Political authorities, therefore, need to show respect for this private domain of the individual. According to Berlin, this notion of negative liberty or 'freedom from' refers to a widespread, 'normal' understanding of the term and coincides with the main thrust of English philosophy. Freedom of choice, noninterference, and the distinction between public and private define the core of this meaning of liberty. Berlin is fully aware that however high the value of liberty, there are other values making legitimate claims too: equality, justice, solidarity, etc. Yet, it would be a dangerous 'confusion of values' to confound liberty with those other values. "Everything is what it is: liberty is liberty, not equality or fairness or justice or culture, or human happiness or a quiet conscience" (Berlin, 1969: 125).

Berlin holds that the value of freedom has its all-embracing meaning predominantly in civilized societies and even there most of all for established citizens. "Freedom for an Oxford don (…) is a very different thing from freedom for an Egyptian peasant" (Berlin, 1969: 124). Berlin is ready to admit that first things come first. If these 'first things' are medicine or clothes, they may have a higher priority in the life of an Egyptian peasant. But even here, Berlin assumes, the peasant will not be able to carry on without a minimum of freedom. He is not willing to follow the argument – noble as it may seem – that as long as there is oppression and exploitation in the world, as long as some parts of the world are still in chains, one has to sacrifice one's freedom. It may well prove necessary to restrict freedom in order to avoid misery. But such a restriction is a sacrifice and not an enlargement of freedom.

Negative freedom as defined by Berlin is a rather recent accomplishment. "This is liberty as it has been conceived by liberals in the modern world from the days of Erasmus (some would say Occam) to our own. Every plea for civil liberties and individual rights, every protest against exploitation and humiliation, against the encroachment of public authority, or the mass hypnosis of custom or organized propaganda, springs from this individualistic, and much disputed, conception of man" (Berlin, 1969: 127f.). Berlin weaves together liberty, liberalism, and individualism and notes three facts about their relationships. First, while truth and character may happen to flourish particularly well under a political regime of liberty, this is a contingent and not a necessary truth. For Berlin (1969: 128, footnote 1), the common contrary belief is "but another illustration of the natural tendency of all but a very few thinkers to believe that all the things they hold good must be intimately connected or at least compatible, with one another." A negatively free human is equally free to pursue truth or error.

Secondly, this doctrine is rather modern. For the ancient world of the Greeks and Romans, the idea of individual liberty was as unfamiliar as it was to all the other ancient civilizations. Freedom itself is a comparatively recent accomplishment of the Renaissance and Reformation movements.

Thirdly, this doctrine could well be conceived to be compatible with some sort of autocracy and does not automatically entail a political democracy. "Just as a democracy may, in fact, deprive the individual citizen of a great many liberties which he might have in some other form of society, so it is perfectly conceivable that a liberal-minded despot would allow his subjects a large measure of personal freedom" (Berlin, 1969: 129). Indeed, judged historically, benevolent despots are no rarer than democratic demagoguery.

Since Berlin's understanding of the negative side of freedom is so natural and self-evident to him, he spends much more time spelling out the positive side. Positive liberty refers to self-mastery. "I wish to be a subject, not an object; to be moved by reasons, by conscious purposes, not by causes which affect me, as it were, from the outside. I wish to be somebody, not nobody; a doer – deciding, not being decided for, self-directed and not acted upon by external nature or by other men as if I were a thing, or an animal, or a slave incapable of playing a human role, that is, of conceiving goals and policies of my own and realizing them" (Berlin, 1969: 131).

Put together, the negative and positive aspect of freedom, noninterference and self-mastery, seem to be but two sides of the same coin. 'Freedom from' is the defensive; 'freedom to' is the offensive. Despite this apparent inner relationship, Berlin notes a deep internal ambivalence in these two parts of liberty, which tend to clash historically in the 'magical transformation' of freedom into oppression. How can this be explained? The goal of self-mastery is an ideal accomplished by only a fraction of mankind. If leaders step up with a mission to free mankind as a whole, to bring out the better selves of man, the script for liberation is written. Paradoxically enough, however, this process of liberation often turns out to be a monstrous act of oppression: "Once I take this view, I am in a position to ignore the actual wishes of men or societies, to bully, oppress, torture them in the name, and on behalf, of their 'real' selves, in the secure knowledge that whatever is the true goal of man (happiness, performance of duty, wisdom, a just society, self-fulfillment) must be identical with his freedom – the free choice of his 'true,' albeit often submerged and inarticulate, self" (Berlin, 1969: 133).

Berlin analyzes this paradoxical formula, 'liberation as oppression,' in two forms: negatively, as a form of self-abnegation that he calls "the retreat to the inner citadel"; and positively, as 'self-realization' proper in the pursuit of an ideal. The negative way of self-liberation is to shed desires one cherishes yet is unable to fulfill in the environment of one's life. For instance, in an autocratic regime it might be 'wise' to restrict one's own 'free speech.' To shake off the needs that one cannot realize seems a commendable avenue to gain inner peace and serenity. "This is the traditional self-emancipation of ascetics and quietists, of stoics or Buddhist sages, men of various

religions or of none, who have fled the world, and escaped the yoke of society or public opinion, by some process of deliberate self-transformation that enables them to care no longer for its values, to remain, isolated and on its edges, no longer vulnerable to its weapons" (Berlin, 1969: 135f.). This form of 'inner emigration' is typical for the individual and social life under harsh political regimes and in hard times. "Ascetic self-denial may be a source of integrity or serenity and spiritual strength, but it is difficult to see how it can be called an enlargement of liberty" (Berlin, 1969: 140).

The positive form of self-realization relies upon critical reason. The liberating force of knowledge teaches us to distinguish between necessity and contingency. The laws of nature are the case in point. Whoever obeys these laws is not a slave, but, given intelligence and creativity, may use these laws for a mastery of nature. What holds true for nature may equally be valid for society. An enlightened society rests upon the design of institutions no rational person can resist. To obey rational rules and regulations is the only true practice of freedom. "That is the programme of enlightened rationalism from Spinoza to the latest (at times unconscious) disciples of Hegel. *Sapere aude*. What you know, that of which you understand the necessity – the rational necessity – you cannot, while remaining rational, want to be otherwise. For to want something to be other than what it must be is, given the premises – the necessities that govern the world – to be *pro tanto* either ignorant or irrational. Passions, prejudices, fears, neuroses, spring from ignorance, and take the form of myths and illusions" (Berlin, 1969: 142).

If this project of self-mastery is transferred from the individual level to the social or 'organic' level, Berlin says we are entering 'The Temple of Sarastro.' In Mozart's famous opera 'The Magic Flute,' Sarastro's Temple is the embodiment of light, goodness, kindness, decency, and an appropriate conduct of life. Based upon the idea of 'scientism,' all political and moral questions are, in principle, soluble and hence there will be one rational solution. "On this assumption, the problem of political liberty was soluble by establishing a just order that would give to each man all the freedom to which a rational being was entitled" (Berlin, 1969: 145). If there is an objective reason established in a just social and political order, the law becomes an embodiment of liberty. To abide by the law, then, is to be free. Sarastro's Temple turns out to be an example for benign despotism.

But even that is not the end of the story. Berlin discusses recognition and sovereignty as two forces that enter the discourse on liberty. The "great cry for recognition" (Berlin, 1969: 157) has been called 'social freedom.' Is it therefore a third form beyond negative and positive liberty? No. Berlin sees the enormous meaning of mutual recognition in times of decolonization and the movement for independence of formerly colonized states. In his eyes, much in line with his dictum that 'everything is what it is,' recognition is not a question of freedom but a matter of justice, solidarity, and integration. Berlin accepts this need to belong as a very important ingredient in the modern world but rejects the term 'social freedom' as a misnomer.

A similar case can be made with respect to sovereignty. Berlin (1969: 162) reads the French Revolution as "an eruption of the desire for 'positive' freedom of collective self-direction." But even in a Republican democracy the doctrine of absolute sovereignty turned out to be an oppressive new form of benign despotism. The freeing of 'the people' impaired the freedom of ordinary people. This is why for Benjamin Constant, Rousseau was an enemy of freedom despite his republican outlook. For liberals like Constant, Mill, and Tocqueville, democracy can foster freedom only if it ensures that no power but only rights are regarded as absolute and that there are frontiers guarding individual privacy.

"One belief, more than any other, is responsible for the slaughter of individuals on the altars of the great historical ideals – justice or progress or the happiness of future generations, or the sacred mission or emancipation of a nation or race or class, or even liberty itself, which demands the sacrifice of individuals for the freedom of society" (Berlin, 1969: 167). This is the belief in "the notion of a final harmony" (Berlin, 1969: 168). Yet, this idea of a 'final harmony' is a grand illusion. It assumes that all values are compatible and can be fulfilled simultaneously. In fact, Berlin holds, values chronically conflict. We live in a world of 'trade-offs' and cannot have it all and at once. Therefore, choices have to be made that are hard rather than harmonious, conflictual rather than consensual, tragic rather than conciliatory. In his eyes this conclusion "cannot be escaped by those who, with Kant, have learnt the truth that out of the crooked timber of humanity no straight thing was ever made" (Berlin, 1969: 170).

The History of Ideas

Upon first sight, the multifaceted preoccupation of Isaiah Berlin's essays in the history of ideas gives no clue of a systematic approach. His disdain for grand theory or systems, his preference for papers and not books, the wide array of thinkers he dealt with, his own modesty saying he and his work had always been overestimated, all those peculiarities of his oeuvre give the reader the impression that this is the work of an intellectual thinker with idle curiosity. In addition, his elegant style, his conversational tone, the character of his narratives, and his parsimony of conceptual discussion – if compared to the complexity and difficulty of Hegel's or Marx's thought – seem to exhibit the traits of an essayist. What could be the underlying thread in his analysis of Vico, Machiavelli, Herder, Hamann, de Maistre, Marx, Herzen, Belinski, and many others? Apparently, there is no thread.

Yet this impression may prove wrong because it is possible to reconstruct the ensemble of unit-ideas Berlin worked with. Upon closer look, he seeks to understand the three-dimensional constellation of modernity: Historically, he tries to explain the experience of revolution, war, and barbarism in the twentieth century by tracing its intellectual *longue durée* in the eighteenth and nineteenth century; politically, he studies the phenomenon of totalitarianism; philosophically, he seeks to gauge the chances and risks of a critical liberalism with its dual components of liberty and pluralism. Taken together, these three dimensions of the history of ideas, the political problem and the philosophical questions define Berlin's underlying research program.

According to Berlin, the Western discourses in science and ethics may be characterized by three underlying assumptions that have ruled them from Plato to Kant to Hegel and Marx. First, to all genuine questions there is one and only one true answer. Differing answers are deviations from the truth and hence false. This pattern holds true for science and ethics, pertains to scholarly problems as well as to the question of how to lead a good life. Second, these true answers, in principle, can be known even if we do not know them yet. Third, once found the true answers are compatible with one another since true propositions cannot conflict with each other. The realm of true answers forms an organic whole, a totality, a system based upon a logical order devoid of contradictions.

In its history of more than 2000 years, this model was more and more undermined by three rifts. These rifts are turning points in the history of political thought that bring about a revaluation of values in its wake. After such an event, nothing remains the same and a new frame of reference begins to emerge. The first rift in the foundation of this model, according to Berlin (1996: 168–170), came into being by the emergence of Stoicism after the death of Aristotle. Instead of understanding the individual as a public person, it is conceived as an inner being. Instead of conceptualizing the social politically, it is interpreted as ethical. Instead of dealing with a republican social order, anarchy reaches center stage.

The second rift is due to Machiavelli. For Benedetto Croce, Machiavelli's patrimony is, above all, the crucial distinction between immoral politics and moral culture. In the wake of Machiavelli's legacy, there is the talk of 'Realpolitik,' violence as the *raison d'être* of the State and, in times of crisis, the suspension of the institute of *habeas corpus*. According to Berlin, this famous interpretation of Croce – the antinomy between politics and ethics – puts forward 'a false antithesis.' What Machiavelli achieved is not just "the emancipation of politics from ethics"; "what he institutes is something that cuts deeper still – a differentiation between two incompatible ideals of life, and therefore two moralities" (Berlin, 1998: 289). He confronts the two moral worlds of Christian and Pagan morality and claims their irreconcilability. "One can save one's soul, or one can found or maintain or serve a great and glorious State; but not always both at once" (Berlin, 1998: 294).

This insight triggered such a revolution in moral reasoning that the distinction was later reiterated in different forms: Max Weber (1958) separates the 'ethics of responsibility' from the 'ethics of conviction.' Berlin prefers to distinguish between a 'morality of consequence' and a 'morality of motive.' In the-first case, an ethic or morality reckons with the consequences of one's action; in the second case – as, for instance, a true Christian or a revolutionary would believe – the consequences are up to God or society since values are pursued for their own sake no matter what their consequences are. This central development replaced the monism of the old model of Western rationalism by a dualism that is irreducible, incompatible, and incommensurable. In Berlin's eyes, the discovery of plural moral worlds put the nail into the coffin of the 'great chain of being.'

The third rift was brought about by romanticism. Studying Vico, Hamann, and Herder, Berlin (1990, 1993, 1996, 2002a, 2006, 2013b) isolated three path-breaking movements with another revaluation of values in its wake: Populism underlines the belief in the value of belonging to a group, class or nation; expressivism holds that human action in general and art in particular express the personality of a person or group; pluralism relates to a plethora of values and its incompatibility. No culture is alike; all cultures are different. This genuine heterogeneity cannot be transformed into inequality or hierarchy in the sense that one culture could be regarded as better, higher, or more valuable than another. According to Berlin, Romanticism thus also tackles the Enlightenment idea that nature binds together truth, happiness, and virtue. Once the diversity and incompatibility of values and ideals, ideas, and objectives have penetrated into human consciousness, scientifically grounded concepts of the perfect human being or the perfect social order are no longer possible. To be sure, human beings will always strive for values and ideals in order to improve their lives or the social order they live in. But these attempts at betterment of self and society have to do without the backing of scientific truths or a scientifically certified morality.

Conclusion

In his study of 'Russian Thinkers,' Berlin cited Archilochus' famous line: "The fox knows many things, but the hedgehog knows one big thing" (Berlin, 1978a: 22). Berlin was a hedgehog who championed the idea of liberty. He did so in three respects: as an ideal, a value, and a yardstick; as an ideal that he himself held but that had to be interpreted in order to find out its meaning and snares; as a value that is only one among many competing and conflicting values and whose status and standing has to be checked; and as a yardstick for his history of ideas because the preeminent question for Berlin was always how a complex of ideas fares with liberty. But Berlin was also a fox knowing many things. The concept of liberty was embedded in a critical liberalism and a value pluralism ready to acknowledge the complexity of social and individual life. Berlin was very sensitive to the imminent dangers of totalitarian rule that sprang from ideological attempts to realize a collective vision of the good life, be it communism or fascism. His ardent plea for liberty did not fare well with his concept of value pluralism. How could the universal value of freedom be reconciled with the relativism of value pluralism? People free to choose might prefer equality or justice over liberty, which often enough only means freedom and power for the elites. People might also prefer the sense of belonging over freedom. As a versatile fox, Isaiah Berlin knew all that. But his critical liberalism with its aversion to theoretical system building could not and would not ultimately reconcile these inconsistencies.

Best Worst Scaling: Theory and Practice

Abstract

Best worst scaling (BWS) can be a method of data collection, and/or a theory of how respondents provide top and bottom ranked items from a list. The three 'cases' of BWS are described, followed by a summary of the main models and related theoretical results, including an exposition of possible theoretical relationships between estimates from two of the cases. This is followed by the theoretical and empirical properties of 'best minus worst scores.' The entry ends with some directions for future research.

Introduction

Louviere and Woodworth (1990) and Finn and Louviere (1992) developed a discrete choice task in which a person is asked to indicate the 'least preferred' item in a choice set, in addition to indicating the (traditional) 'most preferred' item; the approach that Louviere pioneered is now called best worst scaling (BWS). Louviere's initial focus was on 'objects,' such as attitudes, general public policy goals, brands, or anything that did not require a detailed description, such as would be required for a consumer product such as a soft drink or a car. Thus, Finn and Louviere (1992) used BWS to examine the degree of concern the general public had for each of a set of food safety goals, including irradiation of foods and pesticide use on crops. Figure 1 contains a BWS question similar to ones used in that study.

Almost immediately, Louviere began applying BWS to more complex items such as attribute levels describing a single alternative (profile), or complete alternatives (profiles) of the type familiar to choice modelers. The former case, requiring respondents to identify the best attribute level and worst attribute level within an alternative, was relatively unfamiliar to choice modelers, whereas the latter case is a 'natural' extension of a standard discrete choice experiment (DCE) in which the decision maker selects the most preferred item (Louviere et al., 2000; Hensher et al., 2005).

BWS was initially used mainly as a method of collecting data in a cost-efficient manner, though Finn and Louviere (1992) did introduce the maximum difference (maxdiff) model for best–worst choice (see below). After a 10-year delay, Marley and Louviere (2005) completed an extensive analysis of BWS as a theory, explaining the processes that individuals might follow in providing best and worst data, and presenting plausible mathematical forms for such processes; summaries of those, and more recent, results are presented in Section 3. Louviere has recently returned to the use of BWS as a method of data collection (Louviere et al., 2008), in which case its main purpose, via repeated rounds of best–worst choices, is to obtain a full ranking of items in a manner that is 'easy' for respondents and can then be analyzed in various ways.

The remainder of the entry is as follows. Section 2 illustrates the three types ('cases') of BWS that Louviere developed. Section 3 summarizes the basic models, with Section 3.3 summarizing models of ranking by repeated best and/or worst choices; Section 4 presents properties of simple 'scores'; and Section 5 summarizes and discusses future research.

BWS: the Three Cases

Case 1 (Object Case)

Case 1 BWS (as already illustrated in Figure 1) is appropriate when the researcher is interested in the relative values associated with each of a list of objects. These might be brands, public policy goals, or any set of objects that can be meaningfully compared. Once the researcher has chosen the list of objects, (s)he must present choice sets of these to respondents to obtain best and worst data. Choice sets here serve a similar purpose to those in traditional DCEs: statistical designs are implemented that include (some or all) subsets of all possible items which, with suitable assumptions, facilitate

inferences about the value associated with the wider list of objects.

Case 2 (Profile Case)

Case 2 BWS, which was introduced by McIntosh and Louviere (2002), is illustrated in Figure 2 using a question from a dermatology study (Coast et al., 2006; Flynn et al., 2008).

The choice set has the structure of a single profile (multiattribute alternative, see Case 3). However, the respondent is not required to consider the value of the profile as a whole, but has to consider the attribute levels that describe it, and choose the one that is best (most attractive) and the one that is worst (least attractive). Case 2 BWS is popular in health because health care goods/services can be complicated and even pairs of specifications (in a simple DCE) may lead to unacceptable cognitive burden, particularly among vulnerable patient groups. Also, recent theoretical results show that a Case 2 study, in combination with a Case 3 study of choices between the same (or suitably related) profiles, may allow the separate measurement of attribute weight and level scale value (Flynn and Marley, 2012); should such a study be successful, it would solve this classic measurement problem (Anderson, 1970; Marley et al., 2008).

Case 3 (Multiprofile Case)

Case 3 BWS requires a respondent to choose the worst (least attractive) profile as well as the best (most attractive) one in the current choice set. Figure 3 shows an example question from a mobile phone study (Marley and Pihlens, 2012). The additional data provided by worst choices are valuable in many marketing applications, both in terms of better estimation of parameters and in terms of identifying attribute levels that make a product 'unacceptable.'

Models of Best and/or Worst Choice

We use notation that applies to all Cases (1, 2, and 3) and talk of 'choice options' (or 'options') without distinguishing between objects (Case 1), attribute levels of a profile (Case 2), and profiles (Case 3). We also present the results in terms of a numeric 'utility' value associated with each choice option (and, as relevant, with each of its attribute levels), rather than in terms of the utility coefficients ('beta weights') that are standard in the discrete choice literature (Louviere et al., 2000); we do this because various theoretical results on BWS can only be stated and proved in the former notation (Marley and Louviere, 2005; Marley et al., 2008; Marley and Pihlens, 2012).

Notation

Let P with $|P| \geq 2$ denote the finite set of potentially available choice options, and let $D(P)$ denote the *design*, i.e., the set of (sub) sets of choice alternatives that occur in the study. For example, participants might be asked about their preferences for cars by repeatedly asking them for choices amongst sets of four different options: P represents the collection of car types in the study, and each element of the set $D(P)$ represents the set of options provided on one particular choice occasion. For any $Y \in D(P)$, with $|Y| \geq 2$, $B_Y(y)$ denotes the probability that alternative y is chosen as best in Y, $W_Y(y)$ the probability that alternative y is chosen as worst in Y, and $BW_Y(x,y)$ the probability that alternative x is chosen as best in Y and the alternative $y \neq x$ is chosen as worst in Y.

Multinomial Logit Models of Best and/or Worst Choice

Many models of choice are based on extensions of the *multinomial logit* (*MNL*) *model*. The *best choice MNL model* assumes there is a difference scale u such that for all $y \in Y \in D(P)$,

$$B_Y(y) = \frac{e^{u(y)}}{\sum_{z \in Y} e^{u(z)}}. \quad [1]$$

The value $u(y)$ for an option y is interpreted as the utility for that option.

The parallel *worst choice MNL model* assumes there is a difference scale v such that for all $y \in Y \in D(P)$,

$$W_Y(y) = \frac{e^{v(y)}}{\sum_{z \in Y} e^{v(z)}}.$$

Marley and Louviere (2005) present a theoretical argument for the case where $v = -u$, i.e., we have

$$W_Y(y) = \frac{e^{-u(y)}}{\sum_{z \in Y} e^{-u(z)}}. \quad [2]$$

Note that eqn [1] with [2] implies that the probability that $y \in Y$ is selected as *best* in a set Y with scale values $u(z)$, $z \in Y$ is equal to the probability that $y \in Y$ is selected as *worst* in a set Y with scale values $-u(z)$, $z \in Y$.

The MNL models for best choices and for worst choices can be combined in three simple ways to model best–worst choice:

First, assuming the best choices satisfy eqn [1] and the worst choices satisfy eqn [2], the *best, then worst, MNL model* assumes that for all $x, y \in Y \in D(P)$, $x \neq y$,

$$BW_Y(x,y) = B_Y(x) W_{Y-\{x\}}(y),$$

Second, the *worst, then best, MNL model* assumes that for all $x, y \in Y \in D(P)$, $x \neq y$,

$$BW_Y(x,y) = W_Y(y) B_{Y-\{y\}}(x).$$

Repeated choices satisfying a common one of the above models lead naturally to models of rank order data (Section 3.3).

Third, the *maxdiff model for best–worst choice* assumes that the value of a choice alternative in the selection of a best option (u) is the negative of the value of that option in the selection of a worst option ($-u$), and that for all $x, y \in Y \in D(P)$, $x \neq y$,

$$BW_Y(x,y) = \frac{e^{[u(x)-u(y)]}}{\sum_{\substack{\{p,q\} \in Y \\ p \neq q}} e^{[u(p)-u(q)]}}. \quad [3]$$

Models of Ranking by Repeated Best and/or Worst Choice

Thus far, we have discussed models for the choice of the best and the worst option in a set of available options. To the extent that those choices are reliable, it is of interest to consider the use of repeated choices of the best and/or worst option to generate a rank order of the available options, and to develop models for such rankings. For four options, there are eight distinct patterns of best and/or worst questions, any one of which an experimenter can ask a participant to use for the generation of a rank order on those options; and, also, at least eight possible (MNL-based) models of best and/or worst choice for the final rank order. Here, we introduce notation for two such models, illustrated with four-element sets.

Let Y denote a typical choice set; $R(Y)$ the set of rank orders of Y; $\rho \in R(Y)$ a typical rank order (from best to worst) of Y; and $p_{R(Y)}(\rho)$ the probability of that rank order occurring. Let r, s be two indices, each of which can be fixed (throughout a rank order) at the value b (for ***b***est) or w (for ***w***orst). Let $P^{r,s}_{R(Y)}(\rho_1\rho_2\rho_3\rho_4)$ denote the probability of the rank order $\rho = \rho_1\rho_2\rho_3\rho_4$ (from best to worst) when the rank order is obtained by: the first choice is of type r; the second of type s; the third, again, of type r. Then we can have:

1. repeated best:

$$P^{b,b}_{R(Y)}(\rho) = B_Y(\rho_1) B_{Y-\{\rho_1\}}(\rho_2) B_{\{\rho_3,\rho_4\}}(\rho_3). \quad [4]$$

2. repeated best, then worst:

$$P^{b,w}_{R(Y)}(\rho) = B_Y(\rho_1) W_{Y-\{\rho_1\}}(\rho_4) B_{\{\rho_2,\rho_3\}}(\rho_2). \quad [5]$$

The natural first assumption in testing these models is to assume that the best (respectively, worst) choice probabilities satisfy the MNL model (1) (respectively, (2)), and, as needed

by data, generalizations of those models that include a scale factor that depends on the current choice set in some identifiable manner; this scale factor relates to the possibly changing variability ('consistency') of the choices across sets. An example of such a generalization of the MNL model for best choices, (1) is: there is a nonnegative scale factor s defined for each integer 2,3,…, and a difference scale u such that for all $y \in Y$,

$$B_Y(y) = \frac{e^{s(|Y|)u(y)}}{\sum_{z \in Y} e^{s(|Y|)u(z)}}. \quad [6]$$

We then define a *generalized rank ordered logit model* as a set of rank orders that satisfy eqn [4] with the best choice probabilities satisfying eqn [6]. The form [6] is a special case of what Vermunt and Magidson (2005, Section 2.4) call an MNL with *replication-specific scale factor* and of Fiebig et al. 's (2010) *generalized multinomial logit model*; the latter model also includes scale (variance) heterogeneity across individuals.

Scarpa et al. (2011) collected ranking data by repeated best, then worst, choices and fit that data quite successfully with a model based on repeated best choice, i.e., eqn [4], with those choices satisfying a generalization of the model in eqn [6] that included properties of the scale factor s on aspects of the design that took account of the difference between the data collection method (repeated best, then worst) and the model (repeated best); it would be interesting to see if their data could be better fit by a model that matched their data collection method, i.e., eqn [5]. Collins and Rose (2011) fit related models to stated preference data on dating choices.

Maximum Random Utility Models of Choice and Response Time

When treated as a single model, the three models [1]–[3], satisfy an *inverse extreme value maximum random utility model* (Marley and Louviere, 2005; Def. 11). That is, for $z \in P$ and $p, q \in P$, $p \neq q$, there are independent random variables ε_z, $\varepsilon_{p,q}$ with the extreme value distribution. (This means that: for $-\infty < t < \infty$ $\Pr(\boldsymbol{\varepsilon}_z \leq t) = \exp - e^{-t}$ and $\Pr(\boldsymbol{\varepsilon}_{p,q} \leq t) = \exp - e^{-t}$.) such that for all $y \in Y \in D(P)$,

$$B_Y(y) = \Pr(u(y) + \varepsilon_y = \max_{z \in Y}[u(z) + \varepsilon_z]), \quad [7]$$

$$W_Y(y) = \Pr(-u(y) + \varepsilon_y = \max_{z \in Y}[-u(z) + \varepsilon_z]), \quad [8]$$

and for all $x, y \in Y \in D(P)$, $x \neq y$,

$$BW_Y(x, y) = \Pr\left(u(x) - u(y) + \varepsilon_{x,y} = \max_{\substack{p,q \in Y \\ p \neq q}} \left[u(p) - u(q) + \varepsilon_{p,q}\right]\right). \quad [9]$$

Standard results (summarized by Marley and Louviere, 2005) show that the expression for the choice probabilities given by eqn [7] (respectively, eqns [8] and [9]) agrees with that given by eqn [1] (respectively, eqns [2] and [3]).

These random utility models are particularly interesting in the present context because they can be rewritten, and extended, in such a way as to also predict response time (Hawkins et al., 2012).

Extensions of the Models to Case 2 and Case 3

The notation, models, and results (such as for scores, Section 4) are easily extended to Case 2 and Case 3 (Marley et al. (2008) for Case 2, Marley and Pihlens (2012) for Case 3, and Flynn and Marley (2012) for a summary of all cases).

Properties and Uses of Scores for the Maxdiff Model

We now summarize theoretical and empirical results for best minus worst scores (defined below) for the maxdiff model of best–worst choice. Although the theoretical results are not exact for, say, the best, then worst, MNL model, to date no identifiable differences have been found between fits of that model and the maxdiff model (see Flynn et al., 2008; for an example of such fits); hence the score measures are useful for preliminary analyses of the data independent of the model that is eventually fit to the data.

For each option x in the design, the *score* for x (in this particular design) is the number of times option x is chosen as best in the study minus the number of times option x is chosen as worst in the study; we call refer to 'the scores' for these values across the options in the design.

Scores: Theoretical Property 1 (for Cases 1, 2, and 3)

Marley and Islam (2012) state the following terms and results exactly. Assume that one is interested in the rank order, only, of the (utility) scale values in the maxdiff model. An *acceptable loss function* is a 'penalty' function with a value that remains constant under a common permutation of the scores and the scale values, and that increases if the ranking is made worse by misordering a pair of scale values. Let P be a master set with $n \geq 2$ elements and assume that, for some k with $n \geq k \geq 2$, every subset of P with exactly k elements appears in the design (Further work is needed to extend the theoretical result to, say, balanced incomplete block designs. See Marley and Pihlens (2012) for related discussions of *connected designs*.) $D(P)$. Then, given the maxdiff model, ranking the scale values in descending order of the (best minus worst) scores, breaking ties at random, has 'minimal average loss' amongst all ('permutation invariant') ranking procedures that depend on the data only through the set of scores.

The above result actually holds for the class of *weighted utility ranking models*, which includes the MNL for best; MNL for worst; and the maxdiff model for best–worst choice (Marley and Islam, 2012).

Scores: Theoretical Property 2 (for Cases 1, 2 and 3)

The set of (best minus worst) scores is a sufficient statistic. As with the first theoretical property, this one holds for the class of *weighted utility ranking models* (Marley and Islam, 2012; Theorem 3).

Scores: Empirical Properties (for Cases 1, 2 and 3)

The best minus worst scores have been found to be linearly related to the maximum likelihood estimates of the best, then worst, MNL model, and of the maxdiff model, in virtually every empirical study to date. For example, Flynn (2010) obtained this result in a Case 2 quality of life study, and Marley and Islam (2012) present such linear relations for both profiles and attribute levels in a Case 3 study of

consumer attitudes to the installation of solar technology for household electricity production. Such linearity is probably a manifestation of the linear portion of the logistic (cumulative distribution) function; thus, a nonlinear relationship is likely only when the researcher is plotting the scores for a single highly consistent respondent, or for a sample of respondents each of whom is highly consistent and the choices are highly consistent across the sample.

The scores also enable considerable insights to be drawn at the level of the individual respondent. For example, taxonomic (clustering) methods of analysis have been applied to the scores (Auger et al., 2007) and Flynn and colleagues have used the scores to decide which solutions from latent class analyses 'make sense' (Flynn et al., 2010).

Summary and Future Research

Further research is needed to understand the factors affecting the scale factor at different choice depths and the conditions under which the data require different functional forms (models) for best and worst choices. Also, research to date suggests that the class of models with natural process interpretations is different from the class of models with useful score properties. Nonetheless, the scores may give the average applied researcher more confidence, not least in terms of better understanding heterogeneity in preferences and/or scale factors in their data.

Data pooling has normative issues that are particularly pertinent to health economists: for best–worst choice, it is only if all individuals satisfy the maxdiff model that the average of their utility estimates represents the preferences of the 'representative individual' used in economic evaluation. Also, appropriate data pooling exercises (likely involving Case 2 and Case 3 data) may allow the separation of attribute weight and level scale value (Marley et al., 2008; Flynn and Marley, 2012). While the distinction between these two measures is not recognized by traditional economic welfare theory, it offers benefits to health researchers constructing multidimensional health outcome instruments from individual symptom scales: for example, rejection of a simple 'sum-score' aggregation rule necessitates decisions as to what importance weights are to be applied to the individual symptom scales (Fayers and Machin, 2007, p. 218).

Bielefeld School of History

Abstract

'Bielefeld School' has become the collective name of a group of West German historians who developed a specific form of social history defined as 'history of society' or 'Historische Sozialwissenschaft.' This version of social history was theoretically inspired by the work of Max Weber and critically used modernization theory as their points of reference for the historical analysis of modern German, American, and European History since 1800. History of modern society was understood as the dynamic interplay of autonomous subsystems, mainly economy, culture, and power ('Herrschaft'). Thus the history of processes and structures was given priority over the history of political events, of individuals or symbolic (cultural) representations. The explanation of the German 'Sonderweg' leading to the rise of Nazism and the Holocaust was a driving political motive behind the theoretical and methodological program of the School. It was mainly formed by historians trained by Hans-Ulrich Wehler and Jürgen Kocka at Bielefeld University and had their high time during the 1970s and 1980s.

Bielefeld School

'Bielefeld School' has become the collective name of a group of West German historians who developed a specific form of social history defined as 'history of society.' This program was mainly formed by Hans-Ulrich Wehler (born in 1931) and Jürgen Kocka (born in 1941), both teaching at Bielefeld University during the formative years of this school (1971–96 and 1974–88, respectively). This version of social history was theoretically inspired by the work of Max Weber and critically used modernization theory as their points of reference for the historical analysis of modern German, American, and European History, since 1800. History of modern society was understood as the dynamic interplay of three autonomous subsystems: economy, culture, and power ('Herrschaft'). Thus the history of processes and structures is given priority over the history of political events, of individuals or symbolic (cultural) representations. The explanation of the German 'Sonderweg' leading to the rise of Nazism and the Holocaust has been a driving political motive behind the theoretical and methodological program of the school.

The Formative Moment

The specificities of the social history the 'Bielefeld School' developed as their own style of historiography are strongly related to the intellectual situation of German historiography after the defeat of Nazism and German imperialism in 1945. The division of Germany and the political confrontation of the Cold War contributed to the survival of a (both politically and methodologically) conservative mainstream in West German historiography. As a result the international rise of new themes and methods of historical research had no or very limited effect on West German scholarship after 1945 (Berger, 2011). Neither the Annales School nor the American or British social history found many followers in both Germanies. Instead, orthodox Marxist–Leninist historiography (in East Germany) and a 'Strukturgeschichte' informed by the program of the Völkisch historiography of the interwar years were the main varieties of social history available in Germany till the early 1960s (Etzemüller, 2002).

The 1960s were the formative years of the future Bielefeld School whose early members were all born between 1929 and 1932 (with the exception of Jürgen Kocka born in 1941 but joining this group very early in his career in 1968). Wehler and Kocka, the two leaders of the school, and their colleagues were contemporaries of the pre-1968 intellectual situation in West Germany; they got their new intellectual orientations from the US and the UK. Both the fascination of the new social sciences and Western democracy were their starting points and lead to a sharp break with traditional German historiography and its theoretical backbone, a historicism that was practically reduced to a professionally sophisticated history of politics, history of (political) ideas, the history of institutions, and strongly linked with liberal and conservative nationalism (Berger, 2011). The younger historians chose a critical look at the German history of the nineteenth century and particularly of the Empire (1871–1918) focusing on the sharp class antagonisms and the negative role of the Prussian nobility in combination with the authoritarian traditions of the Prussian State. The so-called Fischer controversy starting in 1961 about the responsibility of the German politicians for the outbreak of World War I and the continuities of an aggressive imperialism among the German elites from the Kaiserreich to the Nazi period condensed all these new elements into a new master narrative of contemporary German history, revitalizing the thesis of a German 'Sonderweg,' a German way to modernity different from the Western liberal path, but now judged very critically as a path into moral and political catastrophe (Sheehan, 2005). The 'Bielefeld' School transposed this initially political impulse into a program of a new kind of history based on a broader approach toward the past including mainly the history of social groups and classes and theoretically inspired by the theories of modern societies developed by the social sciences. The rediscovery of Max Weber and his return back into German historical and social theory via Talcott Parsons and American historical sociology were the second disruptive event that gave start to the Bielefeld School.

The political upheaval of the years 1967 and 1968 and the rise of a new leftism (largely inspired by Neo-Marxism, later by French poststructuralism) did not change the intellectual profile and theoretical orientation of the Bielefeld School, now

on their way to organize themselves as a special group with their own program. However, the political turn to the left and the push toward democratic reforms in West Germany largely helped to pave the way for the sudden and quick breakthrough of the new group at the beginning of the 1970s. Their common political background brought most of them in more or less strong relations to the social democratic party and the social liberal coalition, and many of them engaged in the heated public debates of the time about the German (Nazi) past and the interpretation of the Holocaust (the so-called 'Historikerstreit'). They established themselves as public historians gaining high profile in the intellectual debates of West German democracy (Kocka and Budde, 2001; Wehler, 1988).

The Program

The group (at this starting point still rather small but using their networks within a rapidly expanding minority of social democratic or liberal historians) has very early defined their intellectual aims and their theoretical positions. They deliberately used the Kuhn model of scientific revolution through paradigm change as their own strategy for innovation and symbolically burnt all bridges with the 'historicist' past and symbolically distanced themselves from the mainstream of both professionally and politically conservative historians. This symbolic revolution was underpinned by the new critical interpretation of the historicist German tradition established in the Anglo-American world (Iggers, 1968). Confrontation and controversy were used to give profile and unity to the group in the making. Wolfgang J. Mommsen gave the tone in 1970 in his inaugural lecture at Düsseldorf university in announcing a historiography (Geschichtswissenschaft) "beyond historicism"(Cornelißen, 2010). Mommsen criticized the cult of empathic hermeneutical understanding (Verstehen) as opposed to explanation (Erklären), the idol of the biography and the priority of politics (Mommsen, 1971). To transcend these shortcomings, the social sciences and social theory were the new remedies. This turn lead to a series of attempts to better define the new agenda of social history. These were the two headings that suited best the Bielefeld program in the making.

'Gesellschaftsgeschichte' translated the term 'History of Society' coined in 1971 by Eric Hobsbawm but deleted the link to a Marxian view (Hobsbawm, 1974). It expressed the conviction of the Bielefeld School that social history should not be understood as a subfield of historical research – like military, cultural, or political history – but must be developed as a comprehensive approach to history. The analytical unit of inquiry and the theoretical object is 'society' understood as the integrated ensemble of different subsystems (economy, politics, culture) whose past can only be explained by historical processes leading to what social sciences may describe as 'structures' of society. Thus 'Gesellschaftsgeschichte' as a research practice has the aim to identify, describe, and explain the bundle of such processes giving form and unity to a given society. This program concentrated on modern Western societies and their complexities and therefore it heavily depended on different macro theories about the dynamics of the Western World since the eighteenth century. It were mainly American macro sociology, particularly Weberian historical sociology, structural functionalism, and modernization theory that informed the research program of the school, but less as overall big theories of development in sharp competition with Marxism but more as the converging point of a set of theories of middle range dealing with different processes like urbanization, professionalization, industrialization, secularization, and so on. The perspective on these processes should be one of critical inquiry mainly interested in problems of social inequality and of political power. From the beginning, the Bielefeld School investigated the particularities of each process in each region or nation they were studying, seeing their own historical practice as complementary to sociological theory or ongoing empirical research of the social sciences in contemporary society. It was Max Weber who now got highest esteem as the leading social theorist of modernity and therefore often was the reference point when it came to larger models of explanation or choosing of concepts (Wehler, 1973b, 1975; Kocka, 1977, 2011a).

This approach opened the door for the use of comparative methods in historical research as it allowed to define the common (overarching) element (a social structure, a process) linking two or more particular historical processes or phenomena transforming them into 'cases' open for a comparative analysis (Welskopp, 1995; Haupt, 2001; Haupt and Kocka, 2004). It was Jürgen Kocka who from the beginning engaged in comparative research in combination with the use of theoretical approaches (Kocka, 1981). The debate about the German 'Sonderweg' gave further political and moral incentives to comparative studies along national lines (Kocka, 1993). Since the 1980s, the comparative approach got stronger and in 1993 a center of comparative historical research was founded at the Freie Universität Berlin (now 'Berliner Kolleg für Vergleichende Geschichte Europas') (Haupt and Kocka, 2009).

In consequence of this opening to sociological and economic research of the past, the second heading 'Historische Sozialwissenschaft' (history as social science) delineated the ambitious program of an interdisciplinary scholarship or a new discipline integrating the traditions of the social sciences and history. It was Werner Sombart who had first coined the term in 1916 (Lenger, 2010). But what at the beginning of the twentieth century was a well-established tradition in social and economic research turned out to be a new program in the 1970s that was far away from academic reality. The relationship between the social sciences and history did not develop toward the merging of the disciplines but on the contrary toward segregation and mutual distance. The success of the social sciences since the 1970s pushed toward a further specialization and an even more pronounced focus on contemporary society and their problems. Unlike in the USA, historical sociology never established itself as a subfield in West German sociology.

The program of 'Historische Sozialwissenschaft' implies a new understanding of intellectual references and the Bielefeld School created their own intellectual tradition by adopting a long list of scholars from the field of economics and social sciences as founding fathers of the new kind of social history they were creating. The German 'historical school of national economics' (like Gustav Schmoller, Max Weber, Werner Sombart, Joseph A. Schumpeter, or Lujo Brentano) was the most prominent among the new

gallery of forerunners and founding fathers presented in a series of essays on "Deutsche Historiker"(Wehler, 1972–1982).

Their own rapid success during the 1970s and early 1980s changed deeply the intellectual landscape of German historiography. Whereas many historians in the fast-growing academic field of history still regarded the full program with suspicion and refused the style of antagonistic confrontation typical of the early years, they tacitly shared many positions with the Bielefeld School. Social history, the use of social theories of middle range, and the concept 'society' were widely accepted by scholars in modern and contemporary history. But this kind of moderate but general acceptance was accompanied by new challenges. During the 1980s, the international trends of the history workshop movement and of microhistory came to Germany and gave birth to 'Alltagsgeschichte' (history of everyday life) and 'Historische Anthropologie' ('historical anthropology'). Although these new groups shared many assumptions with the Bielefeld School, the leading members of the school refused these new trends engaging in a new polemic controversy. In this case, they could marginalize the new group institutionally but they failed to stop the spread of these new approaches better prepared to the 'cultural turn' as they refused the dichotomy of culture and society (Berdahl, 1982).

Therefore from the late 1980s on, the Bielefeld School had to adapt their own theoretical framework to a fast-changing national and international context (Wehler and Hettling, 1991; Kocka, 2010b). The Weberian classicism of the school tended to look old-fashioned and dogmatic to many young historians, their – modestly critic – defense of modernization theory (Wehler, 1975) came under heavy attack from different sides; adherents of postmodernism, postcolonialism, of gender studies, microhistorians, and historians reading Bourdieu or Foucault, all refused the framework of a theory that seemed as the last bulwark of intellectual defense of the West in a kind of never ending cold war. Younger historians trained in the Bielefeld School started to distance themselves from the earlier positions of the school. They proposed a variety of revisionisms giving birth to a pluralism that blurred the differences toward other positions inside the discipline. Firstly, modernization theory was given up in favor of concepts of modernity. Another option was to accept the 'cultural turn' and to give up any priority for socioeconomic explanations and macro theories (Daniel, 1993). A third option was to remodel the theoretical approaches. Bourdieu's concept of capital, habitus, and field, Giddens' macrotheory of social structure and agency were largely used to renew the program of 'Gesellschaftsgeschichte' (Wehler and Hettling, 1991; Mergel and Welskopp, 1997). A fourth option was to shift the thematic focus away from society toward other units of historical research. Thus a part of the group engaged in taking up the concept of civil society internationally at the forefront since 1990. The latest revision opened the perspective toward global history renewing the exchange with newer versions of historical sociology and macrotheory (Osterhammel et al., 2006). But these revisions of the program did not stop its overall decline. The marginalization of social history has played an important role in this loss of visibility and attraction because historians following the new trends (toward a 'new cultural history' of the political sphere, discourse analysis, or the history of concepts) in general did not follow the theoretical framework of the Bielefeld School, neither in its first nor in its revised versions.

The Group and Its Institutional Backings

The term Bielefeld School itself alludes to the institutional and local backing of this intellectual program. In this, as in other cases of academic groups, 'school' is a very strong term. Seen from within, the Bielefeld School has always been a federation of individuals around a small set of common ideas but a growing list of common institutional interests. It was the expansion of the German educational system and the creation of new universities and new posts in academe that accelerated the formation of the school giving professorships or other independent research positions to the still 'young' historians inspired by the new ideas and the examples of Anglo-American social history. Wehler was nominated professor at the Freie Universität Berlin in 1971, Kocka at Bielefeld in 1973, W. Mommsen (born in 1934) in 1970 at Düsseldorf, R. Rürup (born in 1934) in 1975 at Technische Universität Berlin, Wolfgang Schieder (born in 1935) at Trier in 1971. From the beginning, the Bielefeld School was relying on a much broader circle of historians sympathetic with the social history and the critical revisions of German historiographical traditions but not sharing all theoretical and methodological positions of the group. Thus elder traditions of social history survived and merged into a common practice of research.

From the beginning they were coopting younger scholars like Kocka (born in 1941), H.A. Winkler (born in 1939), or Klaus Tenfelde (born in 1944) at a very early stage of their career. All were about 40 years or younger when they got their first chairs and when they joined their efforts for the creation of the new school. Both the universities of Bielefeld and of Berlin became academic strongholds of the new school, in Bielefeld, Kocka and Wehler were teaching side by side since 1973, coopting new colleagues sympathetic with or openly supporting their program. In Berlin, first R. Rürup, later H. Kaelble, J. Kocka, and H.A. Winkler were teaching. The other members were holding chairs at other universities like Gießen, Düsseldorf, Trier, Freiburg, or Darmstadt. Thus the recruitment of students engaging in the kind of new social history started at many academic points in the 1970s. As long as the academic field of historical sciences was polarized along the internal political and theoretical controversies of the 1960s and early 1970s, adherents of the Bielefeld School could be easily identified. But with the expanding of the field and the fading away of the controversies, the field tended to a new kind of informal consensus and a broad pluralism blurring all fixed lines among schools.

From the beginning the group established strong ties to publishing houses, first Kiepenheuer & Witsch, then Vandenhoeck & Ruprecht, and Suhrkamp, later C.H. Beck ,and got high visibility in an expanding market for academic books (Blaschke and Raphael, 2007). The book series 'Kritische Studien' launched in 1972 soon became the most prestigious place for younger historians joining the group and their program to get published. In 2011, 200th volume was published (a reprint of articles of J. Kocka). In 1975 the first issue of the journal

Geschichte und Gesellschaft appeared. This journal was the most visible and most durable institutional support for the Bielefeld School. Its editorial board brought together the core group of 11 historians more or less closely connected to the program, and five social scientists (two political scientists, two sociologists, and one economist) whose presence underlined the interdisciplinary ambitions of the program (Raphael, 1999). The editorial board was meant to play an active role, but in the end it was a smaller board of insiders who did most of the editorial work. Editor-in-chief from 1973 to 1996 was Hans-Ulrich Wehler. He was mainly supported by H. Berding, Wolfgang Mommsen, Hans J. Puhle, Wolfgang Schieder, and Jürgen Kocka who were frequently present at the board meetings and took over the responsibility for a single thematic issue. Their names reappear among the list of authors with the highest number of contributions to the journal from 1975 to 1994. The journal quickly gained national and international recognition and established itself as one of the leading German historical journals in modern and contemporary history. It was never conceived as a partisan journal and opened its pages to critical voices and debates but in the end became the most visible institution of the Bielefeld School presenting like a showcase the ongoing research and the debates that were judged important among the school members. The editorial board was more or less stable for more than 15 years and it was only during the late 1980s that a first exchange of members took place. The cooptation of eight new members between 1987 and 1989 opened the journal for younger scholars (mainly born between 1942 and 1944) who had established more or less strong ties of collaboration with the core group since the 1970s. A generational break did not happen before the turn of the century when all elder members of the group left the editorial board and when the journal was handed over to historians who had started their academic careers in the 1970s and 1980s often under the supervision of the first generation of the Bielefeld School. This change in the editorial board can be seen as the moment when the journal, now in the hand of the heirs, was not any longer regarded as the flagship of a school. Themes and theoretical points of references have got more pluralistic corresponding to the new intellectual orientations and positions of power among German historians in modern and contemporary history.

Topics of Research

'Gesellschaftsgeschichte' or 'Historische Sozialwissenschaft' defined a program that in itself was open for many versions of historical research. It did not imply a turn to a defined set of themes, not even the 'social' had by definition in itself any priority. The search for processes and their interplay allow a very flexible choice of topics. But in practice, the Bielefeld school took up a set of themes and problems that got first priority: their geographical focus was Germany so that the bibliographies of German social history of the 1980s and 1990s can be read as research records of the school itself (Wehler, 1976, 1993).

The history of social classes and groups in Western societies since 1800 may be defined as the first and largest theme of common research. From the 1960s to the 1980s it was the core field of social history. From the beginning, two tendencies coexisted among the Bielefeld School: one that may be defined as the 'single-issue' approach concentrating at the study of one single social group or class and tending toward a detailed description of the different dimensions of group or class existence (often at a regional level), and the other that prefers a 'relational' perspective seeing classes or groups defined by their relative position and their antagonisms. The second perspective is closer to Marxist approaches and the original definition of 'history of society' by Hobsbawm. As always, many studies combined both approaches in more or less consistent ways. The Bielefeld scholars invested heavily in the study of upper classes in nineteenth-century Germany (both nobility and bourgeoisie 'Bürgertum'), the new middle class professions (like physicians, academics, journalists) and the white collar workers (Kocka, 1981, 1995).

But at the same time, the group shared the general trend of the 1960s and 1970s to link social history to the history of the modern working classes and the labor movement. In itself this subfield can be seen as a cluster of many single issues: the history of the organizations, the class formation as a social and cultural process, the study of industrial labor, and the history of working class culture and consumerism. As a whole, the history of the labor movement was strongly leaning toward political history.

A third topic, often nearer to political than to social history attracted much of the research activities of the 'Bielefeld School.' This field may be called the social historical study of national politics. It focuses on the transformation of social forces, economic interests into political will and power. Hans-Ulrich Wehler has given the model book for this new program of a political history in 1973 with his study on the German Empire (Wehler 1973a, 1985). Later he engaged himself in a long lasting effort to write the history of German society since 1800. It took 20 years to finish the book – more than 5500 pages – interpreting the history of modern Germany as the interplay of three independent but strongly related subsystems (economy, power structure 'Herrschaft,' and culture and as the interfering zone of all three subsystems: the social) (Wehler, 1987–2008). More often, the approach leads to the study of particular political institutions, groups, or processes by including the study of the social background and the economic interests behind the scene. This kind of 'materialistic' approach was particularly at fashion during the rise of the Bielefeld School and ended with a large body of case studies about the impact of social and economic phenomena on the political history of Germany from 1800 to 1945. A particular subfield concerns the political and social history of modern ideologies. Again it were the German versions of liberalism, nationalism, socialism, or antisemitism that were analyzed in a perspective integrating social, cultural, and political aspects.

A quantitative study of articles published in the journal *Geschichte und Gesellschaft* allows to specify the main trends. Political phenomena or political power were the single dominant theme of articles published during the two 5-year periods compared (1975–79 vs 1995–99); more than 43% of the 149 articles were dealing with this issue. Economic processes (14 and 8%), social change (12–14%) were less prominent. Cultural phenomena were more often treated (27 and 30%) respectively. These two snapshots underline the continuities in

the research agenda and they show that the Bielefeld School was much more open to themes of cultural history as the controversies of the 1990s may suggest (Raphael 1999: p. 23). The historical world of the Bielefeld school was mainly a German world (66% of all articles from 1975 to 1999 in *Geschichte und Gesellschaft*) and secondly an Atlantic world including Western Europe and North America. Southern and Eastern Europe came as third and the history of Asia or Africa was at the margins (7 from 336 articles with a geographically identified subject).

Since the turn of the century, the new editorial board has tried hard to turn away from this Germano-centrism inherited by the original program and the new team was deliberately opening the agenda of the journal toward the history of modern Asia, Africa and put global and transnational history to the list of top priorities. But this shift implied a further step away from the original theoretical and empirical program of the school.

International Relations and Perspectives

The strategy of polemic break with German historicism has, as its counterpart, a turn toward internationalization. The 1960s and 1970s saw the establishment of an international rise of social history and the Bielefeld School participated actively in this international trend (Lewis, 2013). British and American social historians played an important role in establishing new contacts and their transfers of ideas were crucial for the integration of the Bielefeld school into this transnational field of research. The younger generation was systematically invited to study abroad and to create their own international networks.

The internationally most visible historian of the Bielefeld group is Jürgen Kocka whose publications were translated since the 1970s in English, French, and many other languages and who actively participated in international debates (Kocka, 1999, 2010a,b, 1980). He has been an academic guest and fellow at Chicago, Stanford, Princeton, Los Angeles, Jerusalem, Budapest, Paris, and Oxford. His high international reputation lead to his election as president of the International Committee of Historical Sciences from 2000 to 2005.

But at the same time, the Bielefeld school shared with most of the other national schools of social history a leaning toward methodological nationalism. In this respect they shared a particularity of social history in general: more than colleagues in other subfields of historical research like intellectual or (international) political history social historians were and still are strongly embedded in the debates on social problems of their own nations making it often very difficult to bridge the gap between the different national perspectives informing the way social historians were constructing their national pasts. The German nation-state was the preferred point of reference and modern 'society' was understood as structured by this political unit. Therefore many members of the Bielefeld school specialized in problems of social history defined in strictly national terms.

Past or Present?

In 2013, the Bielefeld School seems to be more a phenomenon belonging to the past than to the present. As a collective, the group has dissolved into different subgroups and most of their members see themselves now as single parts in a professional field that is no longer divided along clear cut programmatic or political lines. But the intellectual heritage of their program and the many lasting results of their research activities still inform many fields of German modern and contemporary historiography.

Big Five Factor Model, Theory and Structure

Abstract

The psycholexical origin of the Big Five model is sketched, theoretical considerations that have guided the development of the model are given, different structural representations are described, critical notions reported, and cross-cultural findings and its usefulness reviewed. The importance of a paradigm for furthering the field is emphasized, and the lexical Big Five factors are compared with the questionnaire-based Five-Factor Model. Also alternative models are reviewed. Moreover, specifications of the Big Five model are described, both in terms of factor facets, and in terms of representation in the form of circular and hierarchical arrangements of personality traits.

Introduction

The 'Big Five' or Five-Factor Model (FFM) is the personality trait model constituted by the five factors or dimensions Extraversion, Agreeableness, Conscientiousness, Emotional Stability, and Intellect or Openness to Experience. This model emerged from applying the principles of the psycholexical approach to personality (De Raad, 2000). That approach theoretically started with the so-called lexical hypothesis, holding that *our common stock of words, our lexicon, embodies the distinctions, men have found worth drawing. Observations of individual differences that people have found of interest, utility, or importance get encoded by words and expressions into the substance of language*. This hypothesis has been expressed in different ways by the personality psychologists Cattell (1943) and Goldberg (1981), and independently by the philosopher of language Austin (1970), the poet and novelist Themerson (1974), and the psycholinguist Miller (1991).

The early success of the Big Five model was caused, among others, by Norman (1963), and by the seminal psycholexical project led by Goldberg (e.g., 1981). This made Costa and McCrae (1992a) add the two factors Agreeableness and Conscientiousness to their own model until then consisting of Neuroticism, Extraversion, and Openness to Experience (NEO): thus, the NEO-PI came into existence to measure the FFM dimensions. A host of new lexical studies in various languages, often supportive of the Big Five model, and the productive work of Costa and McCrae provided the grounds for McCrae and Costa (2008) to build their Five-Factor Theory, and for claiming that the Big Five factors have causal status.

The Importance of Paradigm and Taxonomy in Building Personality Theory

While the Big Five model is now shared in personality psychology (John et al., 2008), it received frequent criticism from perspectives presenting alternative structures (e.g., Ashton and Lee, 2007; Saucier, 2003; Zuckerman et al., 1993) and from studies focusing on cross-cultural replicability of trait factors (De Raad et al., 2010).

For long, personality psychology had been criticized for lack of a paradigm or a shared model. Eysenck (1991) argued that the development of a taxonomy is a prerequisite for furthering any scientific field. John et al. (1988), who defined taxonomy as "a systematic framework for distinguishing, ordering, and naming types and groups within a subject field" (p. 172), compared the importance of a taxonomy in personality with the Linnaean taxonomy that spurred the development of biology as a natural science. Stelmack (1997) paralleled the importance of personality taxonomy with Mendeleev's periodic system of elements in chemistry, stressing the predictive aspects of paradigmatic processes.

The rise of the Big Five model in the early 1990s was applauded as a possible solution regarding the lack of a shared model (Costa and McCrae, 1992a; Goldberg, 1993), yet with stern opposition especially from Eysenck (1992). Now, the Big Five model has secured its place as the dominant model in personality starting in the late 1990s (DeYoung et al., 2007; John et al., 2008). This could be concluded by the sheer number of publications, but, more importantly, by the models' significance in predicting many important life outcomes (Roberts et al., 2007).

Despite the accomplishments in organizing the scattered field of personality, the Big Five was criticized as an atheoretical approach (Block, 2010; Eysenck, 1992). While some claim that the theory underlying the Big Five model is still in development (DeYoung et al., 2010), McCrae and Costa (2008) presented their Five-Factor Theory, aiming to explain the genetic, biological, and causal underpinnings of each dimension. Regardless of the current status of Big Five theory, one can conclude that in just two decades, personality psychology came a long way from a disjointed field to taxonomy building, a shared model, and a prospective personality theory.

The Lexical Hypothesis in the Context of Everyday Differentiation

Everyday conversations relate for a large part to behavior and traits of self or other. Ideas about people are put into words, and when there is lack of words, new words are invented. The practical usage provides feedback on the effectiveness of such

words. Terms like *egoistic*, *aggressive*, or *shy* that have proven useful for their capacity to represent and communicate experiences may end up in the lexical storehouse. The more often a trait or disposition is observed in behavior, the greater the chance that the trait is labeled and that it becomes a communicative commodity.

That lexical archive with its enormous differentiating potential forms the rough material for the construction of a scientifically acceptable medium to describe personality traits. A problem is that everyday language is not a neutral language. The lingual elements that stood the survival test, are loaded in various respects.

Trait words are often contaminated by their context of development and application. For example, the meaning of *devout* and *compassion* is particularly articulated under the influence of Christian values. *Jovial* stems from astrology, *radical* has political connotation, and *neurotic* is from psychology. The extravert was once described as spiritually poor and superficial and the introverted as high and inwardly rich. Now, the introverted is rather the eccentric and individualistic and the extroverted is energetic and sociable. Some words are used only in specific contexts – they are region specific – belong to a certain jargon, or serve a fashionable purpose. As invectives words can become the verbal vitriol with which sometimes reputations are ruined and people are brought to stand apart. So, any effort in exploiting everyday language for scientific purposes needs to show awareness of the fact that many trait words are imbued with contextual information.

The Use of the Dictionary for the Development of a Shared Model of Personality

It took a long time for the scientific study of personality to recognize the value of natural language for the development of a shared model. The psycholexical approach usually involves the use of a dictionary as the tangible representation of the lexicon. The first who pointed to a dictionary as a valid resource was possibly Galton (1884), estimating that roughly 1000 words might be used to describe character. Allport and Odbert (1936) selected all (almost 18 000) personality-relevant words from Webster's unabridged dictionary, 50 years later. Those words were classified into four categories, differing in importance for the description of personality for everyday conversation and differentiation, thus taking into account the contextual issues mentioned above. Those categories were 'Neutral terms designating possible personality traits,' 'temporary moods or activity,' 'evaluations,' and a 'miscellaneous' category. The first group contained most clearly 'real' traits of personality (pp. 24–38).

Block (1995) criticized the ordinary language origin of the trait concepts. Earlier, Costa and McCrae (1992b) and Eysenck (1992) disputed the criteria to arrive at basic dimensions of personality. Much of these disputes relate to personality dimensions found elsewhere in the personality literature, and which were hardly visible in the Big Five framework. Some of those dimensions covered specific areas of interest, such as locus of control (Rotter, 1954) and ego development (Loevinger, 1976); other dimensions were part of alternative multidimensional systems.

John et al. (1988) summarized the main criticisms, including the laypeople origin, the contextual loading, and the additional complication of communicability across languages. Saucier and Goldberg (1996) agreed that the natural language has shortcomings, but they argued that it represents the best approximation of the total population of personality variables. Wiggins (1973) concluded that "we can hardly afford to ignore such a storehouse of accumulated wisdom as a natural starting-point for the study of behavioral attributes" (p. 329). In addition, the lexical approach minimizes a prestructuring of variables according to theorists' preconceptions of personality (Saucier and Goldberg, 1996; De Raad, 2000). Hofstee (2003) argued that one can dispute that ordinary language is not subtle enough for scientific purposes, yet, in studies with questionnaires built on expert language (e.g., Digman and Inouye, 1986), the Big Five were also recovered.

Working on Allport and Odbert's first category, the neutral or 'real' personality traits, including about 4500 terms, Cattell (1943, 1947) built a system with 16 intercorrelated primary factors. None of the later studies using Cattell's variables, however, was successful in replicating that many factors but rather arrived at a much simpler structure with five independent dimensions (see Norman, 1963). Since Norman's (1963) study, those five factors had been referred to as the 'Norman five,' but dubbed the 'Big Five' by Goldberg (1981) in whose work the fifth factor shifted labels from Culture to Intellect (Goldberg, 1993). In the late 1980s and 1990s, the lexically based taxonomy approach was followed in many languages, mainly in Europe, with the replication of the Big Five being most successful in Germanic and Slavic languages (Saucier, 2009).

Intellect or Openness to Experience: A Historical Difference of Opinion

John (1990) observed that there seemed to be no *single* Big Five. Referring to different Big Five studies, the variation in factor naming was striking, with the clearest differences for factor five, referred to as Intellect (or Culture), but also as Openness to Experience (Costa and McCrae, 1985). The Intellect label proceeded from lexical studies, and emphasized 'intellectual' traits such as intelligent and insightful, and Openness to Experience proceeded from a questionnaire approach and emphasized 'open' traits such as imaginative and artistic. The question about the precise meaning of the fifth factor had led to a special issue of the *European Journal of Personality* (De Raad and Van Heck, 1994), showcasing the difference in perspective of the lexical and the questionnaire approach.

The difference of opinion was about what should be considered as important differentiating traits. Costa and McCrae (1985) adopted Openness to Experience from Coan (1974), as the concept that should capture the contents of a cluster of traits in their own work, they had referred to as an Experiential Style dimension. Coan had developed the Openness to Experience scale on the basis of a study using a battery of existing instruments. Coan distinguished various facets for his Openness to Experience scale, and Costa and McCrae (1985) adopted six of those facets for their own purpose. That facet-differentiation for Openness to Experience seemed

to have dictated a similar extension for the other Big Five factors in Costa and McCrae's (1992c) instrument.

Although the difference in perspective between the proponents of the 'lexical Big Five' and the FFM are frequent and sometimes heated, the adoption by Costa and McCrae (1992b) of the two 'lexical' personality dimensions, Agreeableness and Conscientiousness, was incremental in popularizing the Big Five model and it can be construed as a test of its usefulness. The work of Costa and McCrae expanded the five factors from the domain of language and trait-descriptive words to the domain of questionnaires and led to accept the model by more researchers and ultimately formed a step forward to building a theory embedding the Big Five.

The questionnaire origin in Coan's work may be responsible for the expansion of semantics of factor five, in comparison to what the lexical approach had generated. In line of the above critics, McCrae (1990) argued that Openness to Experience is inadequately represented in natural language trait terms. However, Mulder (2006) demonstrated that, in Dutch (De Raad and Barelds, 2008), there is no problem finding a sufficient number of descriptors in the natural language to reliably define both the domain of Openness to Experience and the corresponding six facets.

Interestingly, DeYoung et al. (2009), who used the fMRI in relating working memory with Intellect and Openness, found that Intellect was correlated with working memory accuracy and brain activity, while Openness was not. Moreover, the authors interpreted the neural regions involved in the association between working memory and Intellect as a neural substrate of Intellect.

From Factor Model to Big Five Theory

Regarding the Big Five theoretical status today, there are two groups of thought: one sees that the transition from the Big Five model to theory is still in progress while the other finds that shift has already been achieved. For the Big Five framework to be considered a theory, the first group (e.g., DeYoung, 2010a; John and Naumann, 2010; Srivastava, 2010) specified conditions to be fulfilled, such as an explained evolutionary basis, an account of developmental aspects, an explanation of the underlying psychobiology, a specification of the hierarchy in the system, cross-cultural replicability, and more. The second group (e.g., McCrae, 2010; McCrae and Costa, 2008) postulated the Five-Factor Theory claiming all or most of the conditions above to be answered, with the five dimensions being universal, and with strong biological and genetic bases. Maybe their strongest claim is that traits constituting the five factors are not just descriptive, but represent causal influences that have effects on lives of all persons. The key components of their theory include the five factors as biologically based tendencies, characteristic adaptations covering the developmental aspects and learning experiences, the self-concept as a sort of derivation from the adaptations, and external influences. With the exclusion of the biological bases, these different components are assumed to be connected through dynamic processes.

One major criticism of the theory, as acknowledged by the authors (McCrae, 2010), concerns the dynamic processes that are so prominent in the theory, yet not explained in detail. In order to have a model to be shared by others, more substantial research regarding the major issues has to be undertaken. This has in fact begun in some areas such as personality neuroscience or linking the Big Five with the brain structure (e.g., Adelstein et al., 2011; DeYoung et al., 2010), and in the biology of traits (cf DeYoung, 2010b). Regarding developmental aspects, much research has been done already (cf Mlačić and Milas, in press), as well on the evolutionary basis of the five factors (cf Buss and Hawley, 2010).

The Big Five/FFM Dimensions and Lower-Level Constructs

Just as they were firm in claiming that the Five-Factor Theory is indeed a theory, Costa and McCrae (1992c) claimed that each of the Five Factors consists of exactly six facets, or lower-level constructs, thus forming a set of 30 facets. Openness to Experience, for example, comprises facets of Fantasy, Aesthetics, Feelings, Actions, Ideas and Values.

Contrary to FFM, the work on the lexical Big Five subcomponents or facets was far from being in agreement. The number of facets ranged from only a few to nine per dimension (Goldberg, 2014). Those nine facets came about in the work of Hofstee et al. (1992), generating a total of 45 facet-scales. Peabody and De Raad (2002) analyzed the psycholexical work in six languages and reported six facets for Extraversion, four for both Agreeableness and Conscientiousness, three for Emotional Stability, and five for Intellect. DeYoung et al. (2007) collected data on the 30 facet-scales from Costa and McCrae, and the 45 facets-scales originating in Hofstee et al. (1992), thus producing 15 facet-scales per Big Five factor domain. DeYoung et al. (2007) proposed a two-level hierarchy where the 15 narrower facets make 2 broader facets for each of the Big Five. For Openness to Experience, for example, these findings were roughly in agreement with Griffin and Hesketh (2004) and Mulder (2006), who distinguished a broader facet Openness to internal experiences (poetic, fantasy, and sensitive) and a second broader facet Openness to external experiences (ideas, broad interests).

Apart from such matters of detailing the Big Five domains, the contents of the Big Five factors may well be summarized as follows: Extraversion generally relates to the approach of the individual to the social and material world in an energetic manner (John and Srivastava, 1999). Agreeableness mostly relates to prosocial behavior (Graziano and Eisenberg, 1997). Conscientiousness mostly relates to impulse control and conformity (Hogan and Ones, 1997). Emotional Stability, representing the one pole of a dimension that has Neuroticism as the other pole, is the factor that is omnipresent in psychological research, especially in clinical psychology. De Raad et al. (2010) found that the Emotional Stability/Neuroticism factor appeared relatively weak in cross-cultural lexical studies, which contrasts with its historical prominence. It is possible that Emotional Stability has lesser representation in most natural languages, in comparison to clinical psychology, where its appreciation has led to many nuances of emotional experiences. Finally, the fifth of the Big Five relates to such traits as imagination, fantasy, creativity, and talent (cf Goldberg, 1993; John et al., 2008; Peabody and De Raad, 2002).

Big Five Alternatives

Because of its number of factors, the most obvious alternative for the Big Five seems to be Zuckerman's alternative five-factorial model (e.g., Zuckerman, 2002). This alternative started from the assumption that important traits are assumed to have a biological-evolutionary basis, and it had its origin in studies of temperament and of psychobiological studies. Some other studies with a similar origin are Eysenck's (1967) Giant Three (Extraversion, Neuroticism, and Psychoticism), and Strelau's (1983) Pavlovian theory-based model of temperament.

Assuming the comprehensiveness of the Big Five and their trait semantic coverage, an important question for competing systems is whether they account for more or less the same phenomena. According to Zuckerman (1984) human traits are best studied in comparison to animal behavior and he has made strong efforts in demonstrating that *sensation seeking* is a basic trait underlying both human and animal behavior. In a study using Costa and McCrae's five factors, Eysenck's Giant three, and Zuckerman's five factorial alternative, it turned out that those alternative factors had strong relations to the Big Five, except to Openness to Experience. Hogan (1983), who shares evolutionary elements with Zuckerman's model, combines it in his Socioanalytic theory with elements of interpersonal theory, focusing on interpersonal competence and effectiveness. In a study where seven Hogan Personality Inventory scales were combined with measures of the Big Five, the different measures covered largely the same field of trait semantics (Hogan and Hogan, 2002).

Cloninger (2009) listed 36 often cited, well-known personality theorists, such as James, Freud, Maslow, Kelly, Bandura, and Buss. This historical flock of theorists represent different theoretical perspectives from which many differential dimensions have been generated, such as achievement motivation, field dependence (dealing with information), sensation seeking, dispositional optimism, and locus of control (control over the environment). Some of those topics have faded away, and others were expected or even predicted to disappear from the stage, but reappear sometimes vigorously (cf Pervin, 1990). It is important to understand that the Big Five system does not tell the whole story of personality. It is a comprehensive and differential descriptive system that is understood to form a rich starting point for further specification. Issues, such as change, unconscious processes, and heredity of traits are not contained in the lexical trait vocabularies. Yet trait taxonomy helps to understand semantically the different features of those issues; moreover, empirical research around those issues often make use of instruments based on the Big Five.

Psycholexically Based Models Departing from the Big Five

Lexical Big Five models across languages are far from identical. Especially since Goldberg (1981) talked first of the 'Big Five,' lexical studies in other languages were usually undertaken with the expectation of the Big Five in mind. While names of Big Five factors showed variations on the same themes, explicit diversions occurred with different psycholexical ideas concerning coverage of the trait domain, different procedures in arriving at a full trait-vocabulary, and different cultures or languages.

De Raad and Szirmák (1994) reported on a six-factor trait structure for Hungarian, that included a factor Integrity (*veracious*, *just*, *trustworthy*) beyond the Big Five. A similar factor (called Trustworthiness) was found in Italian by Di Blas and Forzi (1999), and in Korean (Hahn et al., 1999). Ashton et al. (2004) found further support for this factor in French, Dutch, Italian, and Polish and thus proposed Honesty (capturing Integrity and Trustworthiness) to be the Sixth factor of personality. Almagor et al. (1995) untightened the rules of selection of trait terms that aimed to exclude evaluative terms and state terms. Following an unrestricted approach, they demonstrated the possibility of seven broad personality factors that included versions of the Big Five, and two additional factors called Negative Valence (e.g., *dangerous*, *vicious*, *malicious*) and Positive Valence (e.g., *refined*, *noble*, *brilliant*) (cf Benet and Waller, 1995). De Raad and Barelds (2008) virtually exhausted the (Dutch) lexicon using trait-descriptive adjectives, nouns, verbs, adverbs, and standard expressions, thus forming an extremely long list of 2365 trait-descriptive items. Principal Components Analysis yielded an eight-factorial structure in self- and other ratings, that included the Big Five or versions thereof, and three additional factors namely Virtue, Competence, and Hedonism.

In a psycholexical research program in Filipino (Church et al., 1997), seven factors were identified in two studies. Four of the factors were quite comparable to Big Five factors. In addition, Negative Valence was identified, Self-Assurance (most similar to Big Five Neuroticism), and Temperamentalness, which had a complex relation to different Big Five factors. A lexically based structure, most deviating from the Big Five was found in Hindi (Singh et al., 2013), where six factors were identified in self- and peer ratings. Three smaller factors had some relationship with the Big Five Extraversion, Agreeableness, and Conscientiousness. The larger three, however, had complex relations to Big Five factors, but were recognized especially to reflect a conception of personality that dates back far into history, but is still alive in everyday interactions, the so-called *triguna*.

Cross-Cultural Findings

Cross-cultural psychologists have often endorsed the universality of psychological characteristics, as can be seen in cross-cultural studies on dimensions such as achievement motivation, anxiety, and authoritarianism (Church, 2000). Mayer et al. (2011) studied the possibility of universality of personality conceptions in cultural traditions as different as Confucianism, Buddhism, and Judaism. They concluded that judging personality was an important aspect of all those different traditions.

The Big Five model has found cross-cultural support generally in two ways; these two are often linked to the distinction between emic and etic (Berry, 1969). The emic approach in this case aims at finding a trait structure that best summarizes the trait domain of a particular language or culture. Linked to this first approach has been the repeated finding that independent psycholexical studies in various

Western languages led to the Big Five structure. Studies comparing lexical Big Five structures from different languages and leading to the conclusion that the Big Five is replicable across those languages are often done through the analysis of the contents of the structures. Notwithstanding the recurrence of the Big Five, the structure is reproduced better in some languages than in others (Saucier and Goldberg, 2001).

The etic approach is typically followed by constructing a trait system (a questionnaire) in one language, and translate it to and apply it in another language or culture. Studies with the Five Factor Personality Inventory (FFPI; Hendriks et al., 1999) in 13 languages gave evidence of the FFPI to be a reliably and valid measure in a large variety of countries (Hendriks et al., 2003). Similarly, studies with the NEO-PI-R (Costa and McCrae, 1992c) showed replicability of the five factors in most cultures (McCrae et al., 2005). A lesson drawn by Allik et al. (2013) from studies like these was that it is apparently easy to transcend language barriers using such personality instruments. Notwithstanding such excellent cross-cultural findings, criticism has been expressed repeatedly, especially from the side of the cross-cultural methodologists (e.g., Berry et al., 2002). An important issue is that translated instruments tend to be relatively insensitive to detect individual differences of interest in the target language. Ashton and Lee (2001), for example, found that certain FFM-Openness to Experience facets were not well applicable in many Asian samples.

Cheung et al. (2011) proposed an approach that would combine etic and emic into an integrated approach. Such a combined approach can be found in De Raad et al. (2010), who compared 14 independently developed trait structures. For each structure, the starting-point was taken in the lexicon of the pertaining language. The trait terms of that language were used to obtain ratings, and those were factored to arrive at a trait structure meaningful to that language. The 14 taxonomies were pairwise compared, after finding a common part of the factor structures on the basis of acceptable translations of items into the languages of a pair. On average, the results indicated that not five, but rather three factors were well replicable across the languages under study. Beyond the first three factors (with traits that are typical of Extraversion, Agreeableness, and Conscientiousness, respectively) the equivalence of factors across languages tend to divert.

Dimensional, Circular, and Hierarchical Characteristics of the Big Five Model

Studies on the Big Five, but also studies of other trait models, are usually based on analyses that produce orthogonal, or independent factors. That structure is imposed upon the data through the application of the psychometric technique, most typically Principal Components Analysis. The underlying ideal that is pursued is the *simple structure*, in which each trait variable loads substantially on only one factor and the loadings on the other factors are close to zero. In such a conception, the factors are rather narrow in meaning, with high-internal consistency and a rather fixed angular position in the trait space (Hofstee, 2003). A simple conception of Big Five trait factors is thus the representation with five independent dimensions. Although there are trait variables like that, in practice, however, the vast majority of trait variables tend to have substantial loadings on two factors.

Because of the fact that clear and meaningful traits usually load on one or two factors, traits are well represented in two-dimensional arrangements. When all variables from a set of variables that load on a particular pair of factors are located in such a two-dimensional arrangement, using the pair of loading as coordinate values, a circular configuration occurs, called a circumplex (Guttman, 1954). In contrast to a simple structure understanding of traits with narrow meaning, a circular arrangement of traits demonstrates the breadth of semantic coverage through the dispersion of the trait items along the circle (cf Gurtman, 1997). Hofstee et al. (1992) integrated the Big Five model and the circumplex understanding of traits in a comprehensive representation.

Several researchers in the field of personality have emphasized the hierarchical representation (e.g., Cattell, 1947; Eysenck, 1970) with relations among traits running from more abstract to more specific. The behavior 'laughing at jokes' is more specific than 'being lively,' which in turn is more specific than 'Extraversion.' Most typically, hierarchies are studied in two ways, a bottom-up approach and a top-down approach (see Goldberg, 2006). The more traditional ones are the bottom-up hierarchies in which one starts with individual items, which are then clustered into semantic groups; those clusters in turn are clustered into larger groups of traits, until the highest level is reached. The more recently developed top-down approach has been applied in Principal Components analyses of traits, in which structures are considered with one factor or component, two factors, up to a structure with the maximum number of factors considered relevant. The factors from adjacent levels of factor extraction are then correlated yielding the hierarchical configuration (cf De Raad and Szirmák, 1994; Mlačić and Ostendorf, 2005; Zuckerman et al., 1988).

Nomological Network and Practical Usefulness of the Big Five

The Big Five model has led to the development of quite a number of instruments to measure the five dimensions, including the NEO-PI-R and the FFPI. An enormous number of studies have been performed relating the Big Five with other concepts. Of special interest here are the relationships that have been demonstrated between all or some of the Big Five factors and a great variety of criteria. Zeidner (2009), for example, concluded that Conscientiousness and Emotional Stability, and to a lesser extent also Openness to Experience, are predictors of learning and achievement (cf De Raad and Schouwenburg, 1996). Barrick and Mount (1991) studied the relationship of the Big Five factors with job performance. The strongest predictor across a range of occupational groups was Conscientiousness. Maladaptive variants of the Big Five (minus Openness to Experience) are argued to play an important role in relation to abnormal personality (Watson et al., 2008), especially also as a more adequate replacement of the categorical DSM-IV scheme. Roberts et al. (2007) reviewed the role of personality traits as predictors of

important life outcomes. Conscientiousness, Extraversion, and Emotional Stability were found to be related to longevity, and Neuroticism is a strong and consistent predictor of relationship dissatisfaction and divorce.

The availability of the Big Five conceptual system, especially in its integration with the circumplex configuration, forms a fine-grained system that can be used for the purpose of understanding the semantics of other conceptual systems. De Raad and Doddema-Winsemius (1999) used it successfully for the classification of a list of instincts. Kohnstamm et al. (1998) found that virtually all free descriptions of persons in their study could be classified in the Big Five system. Passakos and De Raad (2009) described the traits of the many characters in Homer's Iliad using the Big Five system. Johnson and Ostendorf (1993) used the facet-nuances of the Big Five system to clarify controversies regarding the interpretation of the Big Five Factors.

As described in previous paragraphs, the Big Five conceptual framework has played and still does play an important role in theory building. Digman's (1997) study is a good example where Big Five factors from various studies were factored leading to two higher order factors, which, in turn, permit linkage to various existing theoretical systems in personality (cf DeYoung, 2006). The Big Five as part of a hierarchy of factors enhances the cross-cultural understanding of personality traits (De Raad et al., 2014; DeYoung, 2006).

There is still growing potential for the Big Five as organizer in research and in applied fields. Further research on the separate Big Five factors is needed to sharpen their understanding. Critical approaches to the Big Five may turn existing issues resolved. Especially new psycholexical studies with a model, like the Big Five in mind in many nonexplored languages, may render certain concepts more important in the one culture than in the other. It also leads to new tests of the validity of the Big Five system.

Future Directions

The development of the Big Five model into a possible Big Five theory, outlined above, shows that, after a century of meandering, personality psychology, or at least the trait approach, is close in finding a common stream bed. Although the Big Five model has been criticized both within the lexical approach and from other competing approaches, and alternatives were offered, it was successful in surviving as a shared model in personality psychology for more than two decades. That kind of a consensus was rare in the last 100 years since personality psychology emerged as a scientific discipline. The Big Five successfully organized a scattered field pointed to the natural language as a source for the total space of personality variables, generated numerous publications and was linked to many important outcomes. The Big Five model was adopted by researchers and theorists, not just from the trait approach, and was proven nomologically and practically useful.

However, to be considered a theory in the full sense of the word, there are many bridges the Big Five has to cross. The most important pertain to the various levels of the hierarchy and to the consensus on facets and higher order factors, to longitudinal studies of personality in a life cycle perspective, to the brain-behavior connection, to the link between personality dynamics, traits and outcomes, etc. Last, but not least, since the Big Five is mostly the product of the Westernized world, future research should make an important step in conducting the large-scale studies in other cultures before reaching the conclusion on the universality of the model and the prospective theory.

Abstract

Referring to achieved leadership (often contrasted with inherited 'chiefly' rank), 'big man' has come to stand for a type of political organization closely associated with, although not limited to, Melanesia. This article locates the term's early uses, tracks developing analyses, and notes the shifting place of these studies vis-à-vis larger scholarly arguments. Contemporary trends include waning interest in classic comparativist typology building in favor of historically and culturally situated understandings of personhood and social action: attentive to gendered and emergent class relations, to nation-making and governance dilemmas, and to the impacts of international agencies and corporate interests on local communities and environments.

Referring to an informal style of achieved leadership, the term *big man* has come to stand for a type of polity distinguished, for example, from political systems with formally elected offices or inherited ranks and statuses. It is closely associated with, although not limited to, the ethnography of Melanesia (islands in the southwestern Pacific located just north and east of Australia, for example Papua New Guinea (PNG), Solomon Islands, Vanuatu, and Fiji). While prominent in regional ethnography, political anthropology, and social evolutionary theorizing from the 1950s through the 1980s, this construct has become less visible as a focus of research in recent years. Contemporary work reflects a methodological turn away from typology building (and the functional and evolutionary/developmental theories it served). Emphasis has shifted toward historically and culturally situated understandings of personhood and social action: attentive to gendered and emergent class relations, to nation-making and governance dilemmas, and the impacts of international agencies and corporate interests on local communities and environments.

Early Work and Developing Analyses

Big man is the Anglicization of a descriptive phrase *bikpela man* (and variants) – meaning 'prominent man' – common in Melanesian lingua francas (like *Tok Pisin* and *Bislama*) and analogous phrases or terms of reference in that region's hundreds of local languages, e.g., *nema asori* on Tanna (Lindstrom, 1981: p. 902) and *ol onda* in the Mendi Valley (Lederman, 1986b). The term was widely adopted in post–World War II (WWII) Melanesianist anthropology (e.g., Oliver, 1955; Read, 1959; Meggitt, 1967) to refer to male leaders whose political influence is achieved by means of public oratory, informal persuasion, and the skillful conduct of both private and public wealth exchanges. The anthropology of big men comprises both regional ethnography (the sociocultural interpretation of case materials derived from extended field research) and – as this ethnography is puzzling from a comparative perspective – theoretical debate.

Ethnographic Foundations

While a variety of political systems – involving both inherited and achieved positions, and both ritual performances and political/economic displays – have been observed in Melanesia (as throughout the island Pacific) from the early colonial period to the present day, the big man style of leadership is a notable feature of political life in highland New Guinea (comprising independent PNG and the Indonesian province of Papua, also known as West Papua), Bougainville, parts of the Solomon Islands (e.g., Guadalcanal), and elsewhere. Highland New Guinea in particular is distinctive, in anthropology's cross-cultural ethnographic record, for high population densities and communities loosely organized in terms of kinship groups (e.g., 'clans' and 'tribes' associated with named territories). Their horticultural economies are characteristically based on intensive tuber (sweet potato, taro) cultivation and pig raising. Big man societies intrigued anthropologists and theorists of development for opening up the possibility that economic intensification might be possible in the absence of formal political hierarchies (see Section Political Typologies and Developmental Puzzles below).

Ethnographic research began in earnest in the New Guinea highlands only after WWII, when colonial authority was extended throughout the area and tribal warfare suppressed. It continued apace during the 1970s – when most parts of Melanesia made the political transition to independence – and, with shifting analytical and topical concerns, through the final decades of the twentieth century into the new millennium. Early on, it became evident that highland Melanesian socioeconomic life was relatively egalitarian; that is, access to garden land was universal (a flexible concomitant of kin relationships) and systematic differences in access to subsistence means, spouses, and valuables were muted or absent.

Direct participation in clan events was a more or less exclusively male prerogative and a key means by which men advanced their local and regional social standing; however, it was not obligatory. Even for men, collective clan interests did not necessarily take precedence over personal relationships with kin and other exchange partners, relationships in which

women were also involved. Finally, communities did not typically have institutionalized decision-making councils, nor did political or administrative offices exist to be filled. Instead, men earned leadership status by organizing events held in the names of clans and tribal alliances: they motivated their communities to participate by means of oratory, informal politicking, the cultivation of large personal networks of exchange partnerships, and their own personal and household production work.

Despite the lack of formal political roles and structures, during precolonial and early colonial times clans affiliated with one another in regional alliances for warfare and for elaborate ritual performances associated with initiations and fertility cults (some of which involved multiyear planning). People also frequently came together to sponsor competitive displays and exchanges of customary valuables like pigs and pearl shells: festive events in which thousands participated in a coordinated fashion as recipients and donors. Periodic exchange festivals of different scales and degrees of social and political complexity have driven intensive garden production for generations in the highlands and some other parts of Melanesia.

During the colonial period and – after PNG independence in 1975 – continuing into the present day, exchange events also came to incorporate money (e.g., PNG national currency, *kina*) and nontraditional goods of all sorts (e.g., cows, trucks, and cartons of beer). The desire to participate in these events even helped to prompt early participation in wage work and commercial endeavors. Held to mark important life cycle events like funerals and marriages and to constitute or reorder regional alliances between groups, exchange festivals require skillful organizing and long-term planning. They also require the intensive cultivation of sweet potatoes to feed large herds of pigs, which, in turn, are slaughtered to mark important events (not simply for household consumption) and also invested as wealth in the elaboration of personal exchange relationships.

It is in these contexts that the activities of the big man have been critical. Indeed, investigations into the dynamics of political agency associated with big manship were a centerpiece in the matrix of anthropological investigations into gendered social and political forms and, relatedly, into indigenous concepts of personhood and of the morality of social action.

Early in Highlands research, Kenneth Read (1959) noted a tension between culturally sanctioned assertions of personal autonomy and of group purpose. In Euro-American cultures, an apparently analogous tension counterposes naturalized, 'individual' interests to morally obligatory collective interests (e.g., the state). In contrast, Melanesian cultures implicate both differentiating and collectivizing interests as different but equally sociable possibilities inhering in a distinctive (and distinctively gendered) concept of personhood. Personal autonomy is enacted in the creative elaboration of networks of kin and exchange partners (affines, friends). Each person's social network makes possible the enactment of interests that converge partially – and may also regularly conflict – with the collective (and, in Highland New Guinea, typically male) projects of clans. While the composition and size of exchange networks reflect the contingencies of personal effort (as in the case of friendship circles in Western societies), clan affiliation and rights to land are givens. One generally belongs to one's parent's group, inheriting homesteads and garden land through one's father or mother, although conventions vary across Melanesia and involve considerable flexibility on account of a pervasive recognition of multiple bases for membership and land claims (e.g., Lederman, 1986b).

Against that background, big men make their names not simply by mobilizing wealth for personal network ends – like staging impressive funerary wealth distributions and generously supporting their exchange partners when the latter stage events – but also by successfully orienting their own and their clansmen's respective network interests to collective projects. They persuade fellow clan members to organize their personal, often divergent network affairs to advance common clan events. By enabling events like large-scale wealth distributions between tribal and clan alliances – strengthening the reputations of these named collectivities by demonstrating their organizational capacities – big men augment their group's reputation ('name') in the very act of augmenting their own renown.

In all this, their influence is personal and ephemeral relative to that in societies with inherited rank or with formal councils. This absence of structurally reproduced power has given Melanesian communities a reputation for egalitarianism (among men, if not between men and women). Men with leadership ambitions work to develop personal access to resources within and outside their communities. They achieve fame and influence by using local and regional social networks as bases for organizing collective wealth prestations. By means of both public oratory and private persuasion, big men work to add a certain collective value to actions that would otherwise be everyday and personal.

These events therefore make and remake clans and tribal alliances, which were means for collective defense in the precolonial era. In recent generations, they have been important bases for launching commercial endeavors – for example, cattle herding, coffee plantations – and have also constituted social springboards for provincial and national political careers.

Political Typologies and Developmental Puzzles

In post–WWII anthropology, ethnographic accounts from Melanesia and Polynesia were influential in modeling sociopolitical ideal types (respectively, big man societies and chiefdoms). Such typologies were central to theories of cultural evolution and economic development, of special interest to anthropological archaeologists (who reconstruct the long-term social histories of human populations from material evidence: see Section Anthropology of Big Manship in a Wider Field below) and also to social theorists both within and outside of sociocultural anthropology. For the most part, theories of social evolution assumed that less economically productive societies characterized by limited social differentiation and political decentralization tend to give way, over time, to more productive types characterized by elaborate divisions of labor and centralized, hierarchical political systems. They posited a series of functional interdependencies among variables like population density, technology, the organization of production, 'surplus' production, and sociopolitical stratification (see Lederman, 1986a). Against this background, the big man societies of Melanesia are intriguingly anomalous.

Marshall Sahlins's (1963) typological comparison of the Polynesian chief and Melanesian big man – perhaps the single most influential argument concerning Pacific polities – established the figure of the leader as key to arguments concerning their societies' historical fortunes. With Polynesian chiefs as a developmental standard, Sahlins highlighted the limited coercive power of the big man in mobilizing wealth for public prestations, and identified these limits in the refusal of his clansmen (understood as his political supporters in regional interclan prestations) to put up with his increasingly unreciprocal behavior.

Viewed from this perspective, evidence of large-scale, intensifying, and expanding systems of wealth exchange in Melanesia was puzzling. Ethnographically grounded arguments by Mervyn Meggitt (1967), Andrew Strathern (1971), and others with extensive fieldwork experience in highland New Guinea demonstrated that – while relations between men (dominant in wealth exchange) and women (mainstays of horticultural and pig production) were conflictual – relations between leaders and their fellow clansmen were not predominantly extractive (as Sahlins had supposed). Instead, big men were able to tap labor and other resources in groups other their own by means of personal exchange networks.

Meanwhile, a convergent line of research – bent more on understanding economic change than sociopolitical systems – developed a comparison between Melanesian exchanges and capitalist markets. Dubbing Melanesians and particularly their leaders as 'primitive capitalists,' this work emphasized apparent similarities between local orientations and Euro-American cultural values like personal achievement, competition, material wealth, and financial reinvestment. For example, Scarlett Epstein (1968) labeled Tolai leaders 'primitive capitalists'; and Ben Finney (1973) argued that these similarities culturally and psychologically 'preadapted' Goroka big men for capitalist development.

Indeed, during the colonial period, highland Papua New Guineans were notably entrepreneurial. They reinvested wealth in commercial enterprises, like trade stores, rather than simply spending cash incomes on consumer goods.

These lines of research came to an ambivalent resolution in the 1980s and 1990s. Specifically with respect to the anthropology of big men, Maurice Godelier (1986) centered attention on the structure of marriage exchanges in an argument meant to suggest that the big man type – with its emphasis on the manipulation of wealth – is not as typical of Melanesia as earlier ethnography implied. In communities where marriage conventions de-emphasize bride wealth (transfers of wealth for persons or their capacities) in favor of 'sister exchange' (transfers of persons for persons), he argued that one observes not big men but 'Great Men,' varieties of male prominence (notably initiation cult leaders) founded on ritual expertise. Some recent work in areas of Melanesia whose local political systems are conventionally characterized in terms of inherited rank have found Godelier's Great Man construct surprisingly apt (Barker, 2012).

Nevertheless, Godelier's position followed the classic pattern of using ethnographic cases to construct political economic types as elements in hypothetical developmental sequences. It made diverse cases comparable and capable of being organized as a progression but at the cost of assuming that these cases shared a common commitment to the maintenance of male collective (clan) interests. The Great Man idea also situated big manship on the frontier of market capitalism. However, this strategy of comparative analysis was already under siege ethnographically and theoretically by the mid/late 1980s.

Contemporary Trends

The relative decline in research on big manship as an ethnographic focus in its own right, during the 1990s and 2000s, is part of a long-standing disciplinary trend away from deploying ethnography for comparativist projects of developmental modeling and toward treating ethnography as a means for understanding culture histories.

Rethinking Anthropology, Rethinking Big Manship

Typology building and developmental theorizing, common in early to mid-twentieth century sociocultural anthropology (and political anthropology particularly), treated cultures as objectively identifiable, historically stable, socially boundable units of comparison. Over the past 30 or 40 years, however, a widespread theoretical reorientation in sociocultural anthropology from (as Clifford Geertz put it in his well-known 1983 essay, 'Blurred genres') a 'laws and instances ideal of explanation' modeled on the natural sciences 'toward a cases and interpretations' ideal drawn from the humanities undermined the very idea of bounded, stable, objective cultural units in favor of situated, reflexive accounts of cultural process more amenable to mutual critical translation than to positivist comparative analysis.

On the whole, Melanesian anthropology has not only reflected but also spearheaded these transformations in comparativism and the 'culture' concept (e.g., Roy Wagner's 1975 *Invention of Culture*). In this new staging, big manship has moved out of the analytical limelight, although not out of sight. Hardly relics, big men are everyday facts of life in the rural and urban communities and the provincial and national governments of twenty-first century Melanesia. The shifting array of contradictory values, beliefs, and rhetorics about big men are equally contemporary. They constitute postcolonial transformations of what Sahlins (1963) referred to as the 'Melanesian contradiction': the already delicate ethicopolitical balance that successful leaders had to maintain between reciprocity and exploitative self-advancement in rural communities a generation ago, now made orders of magnitude more difficult by its articulation with market logics and the politics of nation making.

During the 1990s, investigations into big manship became absorbed into a wide variety of academic, policy-oriented, and community-based projects concerned to understand and intervene in the 'emergent forms of life' (in the sense Michael Fischer developed in his 1999 *Annual Review* essay by that name) characterizing contemporary Melanesian experience. It therefore makes little sense to separate the anthropology of big men from these other literatures. Nevertheless, while these projects do not identify themselves with the 'anthropology of big men' as such, they do still acknowledge portions of that

foundational literature as historical grounding for a remarkably wide range of freshly conceptualized research foci, including gender relations and 'engendered' violence, socioeconomic transformations (e.g., emergent class relations and the social and environmental impacts of globalization and extractive industries), and the dilemmas of governance. The following paragraphs sample these themes.

Melanesian gender studies have long directed attention to divergent and conflictual perspectives and relations within communities. While 'sexual antagonism' was a well-developed theme by the 1970s, the past two decades' work historicizes regional experience and sets it in a global context (e.g., Jolly and Stewart, 2012). It renders the male-centered (and certainly male leader-centered) typification of whole cultures analytically unusable and big manship a decidedly qualified value (e.g., Lederman, 1986b, 1990, 1991; Godelier and Strathern, 1991). This research has attended to gender ideologies and gendered practices as grounds for making sense of conflicts between and among men and women, particularly in relation to emergent forms of female political and economic action and leadership, like the 'Wok Meri' movement in the Eastern Highlands (Sexton, 1990) and Kulka women's club intervention in a tribal war in the western Nebilyer Valley (Rumsey and Merlan, 1991). These gendered engagements are transforming local ideas about 'maleness' that long underpinned big manship and associated ideas about collective social forms (e.g., male initiation 'cults').

In recent years, anthropologists have also encountered mirror images of the big man that deploy its metaphoric value for new ends. For example, describing local perspectives on the past generation's social transformations among Dano speakers in the upper Asaro valley of PNG – which foreground increased crime and economic inequality – Thomas Strong (http://anthropology.nuim.ie/research/why-are-men-papua-new-guinea-highlands-shrinking-0) writes, "People point to men's bodies as further evidence of social decay – they claim that the present generation of men are smaller, weaker, and more fragile than the ancestors" and seek to reinvent both themselves and their culture by various means (including evangelical churches and commercial enterprises).

This theme of 'troubled masculinities' – in the comprehensive sense that Laura Zimmer-Tamakoshi develops in her chapter, "Troubled masculinities and gender violence in Melanesia" (in Jolly and Stewart, 2012) – is by now reasonably well developed in anthropological writing on gender and contributes to a contemporary cross-disciplinary interest in the dark side of economic and political change.

Complementary work dissects incipient class relations as Melanesians situate themselves relative to a roiling global economy (e.g., Gewertz and Errington, 1999) and analyzes struggles over the meaning and value of 'environmental resources' – struggles that mutually implicate transnational and local social agents and frames of reference (West, 2006). Big men have long brokered or actively invited these entanglements, particularly the articulation of gift- and market-oriented projects. While early writers interpreted customary big man activities through a capitalist lens (recall Section Political Typologies and Developmental Puzzles), ethnography of the 1990s and 2000s developed subtle understandings of the moral valences of 'gift' and 'market' as distinct, often opposed, kinds of relations even as their mutual entanglements have ramified.

These subtleties echo in ambivalent and contradictory commentary about the ethics of big men in everyday talk, popular media, and policy discourse. Because customary exchange relations are as much political as economic, references to 'big men' become convenient concretizations of otherwise abstract arguments about both development challenges and governance dilemmas (Sullivan, 2005; see also Section Anthropology of Big Manship in a Wider Field below).

For example, Highland PNG peoples have personified the state itself as a 'big man,' an idiom that collapses the scale distinction between 'local' and 'national' in order to insist on a relationship of equivalence and mutual responsibility between them (Clark, 1992; compare Joseph Ketan's 2004 book, *The Name Must Not Go Down: Political Competition and State-Society Relations in Mt Hagen*). Observations like Clark's make evident the salience of idealized references to 'big men' as political rhetoric. Such references can therefore be productive ethnographic foci for understanding the stakes for Melanesians as the wealth-mediated but community-centered competition (that is, competition premised on a wealth 'commons') with which big manship has customarily been associated confronts – however ambivalently, unevenly, and contingently – structural inequalities associated with neoliberal development (that is, premised on private property and individualist constructs of interests) in the context of ineffectual or absent state regulation.

Similarly, Laura Zimmer-Tamakoshi's (1997) instructive case study of the life and times of Ruge Angiva – a "self-proclaimed 'last Big Man'" of southern Madang Province – reads as a contemporary morality tale about the incompatibilities of traditional big manship and Western style capitalist interests, particularly their respective valuations of community and kin loyalties. Related tensions were evident in Tim Sharp's fieldwork on large-scale betel nut traders based in Mt Hagen. Despite the impressive geographical and financial scale of their enterprises, Sharp (2013) reports that relations among traders recall the interplay of cooperation and competition characteristic of clansmen and big men (see also Mosko, 2013). On the other hand, in a 2012 University of St Andrews dissertation, *The Pattern Changes Changes: Gambling Value in Papua New Guinea*, Anthony Pickles charts the rise of new forms of exchange relations and renown associated with slot machine gambling, which favor "big shots" (see also, e.g., Pickles, 2013). The latter term – which Keir Martin's provocatively titled 2010 article, 'The death of the big men,' analyzes as a linguistic index of the emergence of a new category of unambiguously problematic political elite – is defined in explicit counterpoint to 'big men' of the sort Zimmer-Tamakoshi describes.

Anthropology of Big Manship in a Wider Field

Even though the anthropology of big men is no longer as evident as it once was in Melanesian studies or as discrete

a literature as it used to be within political anthropology, it can be located in a number of other notable contexts.

It is alive and well in recent editions of introductory textbooks in sociocultural anthropology, like James Peoples and Garrick Bailey's 2011 *Humanity: An Introduction to Cultural Anthropology*, where it is used to illustrate leadership styles possible in 'egalitarian societies,' in contrast with leadership typical of 'ranked' societies, but with contemporary cautions concerning the disconnection between such typologies and "the lives of actual people" (p. 293). Big manship is also featured in comprehensive surveys of regional anthropology; for example, Paul Sillitoe's 1998 book, *An Introduction to the Anthropology of Melanesia: Culture and Tradition*, devotes a full chapter to big manship, focusing on customary practices of the Siuai people of Bougainville.

The big man/great man/chief typology also appears (as John Barker noted, *pers. com*. 10 July 2012), "in contexts in which we are discussing/updating the insights of our own anthropological 'big men'." Indeed, two recent critical appreciations of influential Melanesianist scholars – Barker's own 2007 edited collection, *The Anthropology of Morality in Melanesia and Beyond* (a substantive engagement with Kenelm Burridge's work) and *The Scope of Anthropology: Maurice Godelier's Work in Context*, a 2012 collection edited by Laurent Dousset and Serge Tcherkézoff – offer chapters that rethink big manship ethnographically and analytically. In keeping with contemporary theoretical trends, these works contribute to a more thoroughly historical perspective on the politics of shifting contexts for meaningful action.

Over the past several decades, anthropological archaeologists have recognized the general value of 'ethnographic analogies' in reconstructing the living social practices likely to have produced the material remains discovered in their excavations. They have begun to recognize the particular value of ethnographies of big manship in expanding their interpretive imaginations beyond conventional correlations between intensifying systems of production and exchange and hierarchizing political structures (see Section Political Typologies and Developmental Puzzles above) to more historically nuanced scenarios. Encouraging more sophisticated mutual engagement between archaeologists and ethnographers and more sophisticated theorizing and modeling of political action, Paul Roscoe (2000) reviewed the past decades' ethnography of New Guinea leadership. This comprehensive and admirably critical review articulates important cautions concerning comparativism. (By the by, its bibliography also testifies to the attenuation of big manship as a topical focus in the regional literature after the early 1990s, compared with previous decades.)

References to big manship also appear from time to time in contemporary ethnographic reports from outside of the island Pacific, especially in analyses of local political dynamics in the context of 'absent' or contested state influence. For example, in a 2012 Stanford University talk concerning post-civil war Lebanon, Marten Boekelo highlighted 'neighborhood big men' in an account of reworked forms of governance emergent after older mechanisms for the local mediation of the state and central political actors had broken down with the eruption of violence.

The term and its classic anthropological referents appear occasionally in popular media outside Melanesia, where it is used (with a positive valence) to signify decentralized or nonhierarchical influence, e.g., of Internet bloggers, and (with a negative valence) to refer to "crony capitalism" and other distortions of democratic process. For example, in an extended metaphor, an *Anchorage Daily News* article ('Juneau's Big Men should be scrutinized,' 18 May 2012) written by Kenai Peninsula College anthropologist Alan Boraas compared state legislators visiting their districts after state budget negotiations to Viking raiders returning home with the spoils of war, the point being that local leaders reinforce their local political clout by personally redistributing state wealth to their constituents. Referring to Sahlins's Melanesian exemplar, the article asserts that Alaskan legislators "function as 'Big Men'" insofar as their actions bypass the constitutional process mandating state agency control over local budget requests. Legislator-big men act as "gatekeepers to whom citizens come hat in hand." However, while "the state funding system is, at least in theory, transparent, non-government requests via the Big Man system are not" because that system relies on networks of "who knows whom" fueled by bribelike gifts ("a late-evening phone call, a fishing trip").

As if to echo such popular media representations, political and economic policy scholars' diagnoses of the causes of political 'dysfunction' in PNG and other Pacific island nations locate big manship prominently in this picture, although in inconsistent ways. On one side, in a 2007 report, Francis Fukuyama (http://www.sais-jhu.edu/faculty/fukuyama/Governance_PNG.doc) situated the big man as an anchor of indigenous democratic process and as an obstacle to the consolidation of state power. He argued that without a well-developed administrative bureaucracy, the national government has a limited ability to provide basic services like education and health care, especially in rural areas where the continued strength of kinship-based social structures and big manship – "highly unstable coalitions based on personality and patronage networks" – act as checks on the development of strong state control (p. 6). He linked the weaknesses of state agencies to the fact that "Papua New Guinea is arguably one of the most inherently democratic societies in the world." That is, conventions of "prolonged discussion and deliberation" and the 'big man' style of achieved leadership – "constantly subject to challenge and change" (p. 9) – all work against consolidation of strong state institutions. Fukuyama noted, however, that these same decentralizing sociopolitical dynamics also short circuit the development of powerful regional 'warlords' who might be in a position to challenge the state (as in Somalia or Liberia). Fukuyama concluded that governance reform in PNG may therefore depend on the prior cultivation of common national identifications that transcend the local loyalties with which big men are strongly identified.

Then again, other observers of PNG development trends have situated big men at the center of dysfunctional governance itself in diagnoses of the reasons for 'stalled' economic development. Writing in 2012 in the East–West Center's *Pacific Islands Report* (http://archives.pireport.org/archive/2012/April/04-18-an.htm), Helen Hughes associated that

country's "political stagnation" with elections that yield only "a changing roster of 'Big Men' to exploit parliamentary power. Senior public servants share in the spoils." Asserting that "Since the 1970s the Pacific has received the world's highest aid per head of population," Hughes concluded that foreign aid has not promoted rationalized economic development. Instead "aid is regarded as 'cargo'" (a term implying material wealth acquired by mystical means) to be redistributed strategically to curry favor with constituents. Similarly, in a 2005 Australian National University 'State, Society, and Governance in Melanesia' discussion paper (http://ips.cap.anu.edu.au/ssgm/papers/discussion_papers/05_04_dp_patience.pdf), former University of Papua New Guinea political science professor Allan Patience noted shifts in Australian aid policy that were motivated by "security fears" concerning "mutations of traditional ('wantok' or 'bigman') structures of power into virulent forms of crony politics," a political form "resistant to democratic institutions, transparency in government, and conventional state-making strategies" and therefore vulnerable to exploitation by international crime syndicates and terrorist networks.

These core themes of regional development policy analysis are echoed, debated, and countered in opinion pieces and letters to the editor of *The National*, *The Post Courier*, and other Melanesian media, where denunciations or praise of big manship figure prominently in commentary concerning the impacts of Western development agendas on historically Melanesian political and economic forms.

In contemporary discourse among urban elites and rural villagers, the figure of the big man is something of a key symbol. It powerfully condenses several tensions in twenty-first century Melanesian sociopolitical life at the heart of contemporary policy debates about governance. As Nancy Sullivan (2005) and the impressively varied collection of papers on 'the challenges of governance' in the Pacific that she introduces make clear, it stands for a neotraditional vision of properly reciprocal or redistributive sociality in counterpoint to both the alienating impacts of international consumer culture and the disappointing performances of national and provincial state governments. It also stands for the corrupting influence of excessively narrow loyalties and the oppressive dominance in domestic and public life of practices and values historically associated with maleness.

Holding contradictory impulses simultaneously in view is a characteristically anthropological move, whereas both popular and policy discourse tend to simplify or resolve them in some way. Loyalty to kin and expectations concerning material reciprocities can appear as nepotistic corruption or as a bulwark against capitalist individualism. Similarly, calls for the cultivation of cross-sectional national identity can appear as a ploy to undermine the very social resources most reliably available to ordinary people, under present conditions, in their disorienting encounters with multinational corporations and agents of neoliberal political and economic reform. However, contradictions among these points of view are themselves social facts with material impacts on the outcomes of projects that communities and experts care about.

Conclusion

In short, big manship is present both in public discourse at the national and local levels in Melanesia and among national and international development scholars and policy analysts with regional expertise. It is, therefore, a live issue in need of fresh ethnographic attention; this constitutes one rationale for a new generation of anthropological investigations into twenty-first century transformations in this leadership form, its associated social relations, and its shifting rhetorical values among diverse social actors.

Those investigations may be enriched in unexpected ways by continued or refreshed familiarity with an earlier generation's contributions to the anthropology of big manship. Similarly, contemporary anthropological archaeologists may be persuaded to draw on that literature as an exceptionally well-developed source of insights into the workings of decentralized political systems, on which to model their interpretations of the material evidence of past sociopolitical and exchange systems.

New fieldwork and ethnographic writing about big men are more likely to identify themselves with contemporary theoretical and topical rubrics than with the 'anthropology of big men' as such. However, so long as big manship, its variants, and echoes remain a focus of lay and expert attention in Melanesia, anthropological work will continue to enlighten by situating particular perspectives and experiences sympathetically in culture-historical context, and their commonalities and differences critically in juxtaposition.

Bilingual Aphasia

Abstract

The manifestations of aphasia in bilingual or multilingual persons are an important source of data for the study of different recovery patterns, for the elaboration of hypothesis about the organization of the two or more languages in the brain, and in sum for a better understanding of the language representation and processing. It is critical that all languages of a person with aphasia are assessed by means of a cross-linguistically equivalent instrument and that the rehabilitation be done taking into account all of the involved biological and ecological variables.

Introduction

Bilinguals are persons who use two or more languages (or dialects) in their everyday life (Grosjean, 2010) at different levels of communicative competence and proficiency. Many factors need to be taken into account when characterizing bilinguals such as the languages actually known and used, the structural relationships between them, the history of acquisition and use, and the functions of their languages including context and purposes of use. All these factors determine the verbal communicative competence of bilinguals for each of their languages. Verbal communicative competence comprises: (1) implicit linguistic competence that refers to the knowledge inferred from individuals' systematic verbal performance, it is acquired incidentally by practice, it is stored implicitly, and it is used automatically; (2) explicit metalinguistic knowledge that refers to knowledge of which individuals are aware and that they are capable of representing to themselves and verbalizing, it is learned consciously, it is stored explicitly, and recalled voluntarily; (3) pragmatic competence is the ability to select the appropriate linguistic and paralinguistic choices, given the context, the corresponding purposes, and the required effect on the audience; and (4) motivational drive that refers to the complex network of motivations and affects involved in each language acquisition, learning, and use (Paradis, 2004).

Verbal communicative competence of bilingual individuals can be affected as result of different brain damage that produces linguistic and communicative deficits, broadly known as aphasia, with consequences on the bilingual person's life. As bilingualism is a worldwide phenomenon and half of the world's population is bilingual (Grosjean, 2010), bilingual individuals suffering from aphasia are not rare cases but rather a majority of clinical cases (Paradis, 1998a). The study of manifestations, assessment, and rehabilitation of aphasia in bilinguals constitutes one important issue of the neurosciences and applied linguistics, and allows researchers and clinicians to better understand how languages are represented in the brain, how verbal communicative competence may be affected at several levels, and to different extents in the way that languages can be rehabilitated.

Interest in bilingual aphasia appeared in the nineteenth century concurrently with the classical studies of language impairment in brain-damaged patients and with the controversies about the representation of language in various brain centers. Some reports of bilingual aphasic patients appeared after the publication of the Paul Broca's (1861) seminal paper on aphasia but the first classical study on aphasia in bilinguals was written by Albert Pitres in 1895 (Pitres, 1895). In his study, Pitres reviewed several case histories described by contemporary scientists (Bastian, Oré, Rinkenbach, Bianchi, Charcot, and Bernard) and analyzed seven cases that he gathered himself. From these cases, especially from his case number seven, Pitres designed the first theoretical proposal on bilingual aphasia based on the following principles: (1) differential loss, "when a polyglot patient is stricken with aphasia, he does not necessarily lose to an equal extent the use of all the languages he knew before"; (2) differential recovery based on familiarity, "the patient first begins to understand, then to speak the language that was most familiar to him. Ultimately he is able to understand, then to speak the other languages that he knew"; (3) inhibition but not destruction, "the systematic return of the languages occurs in cases where language centres have been shocked or inhibited but not destroyed by lesions…, gradually take up their functional activities again after having lost them for a period of time"; and (4) participation of the same cortical language centers as in monolinguals, "the temporary inertia of the cortical language centres accounts well enough for the sequence of phenomena observed in polyglot aphasics that it is not necessary to bring in the absolutely hypothetical existence of new centres that are especially assigned to each of the languages learned successively by these subjects" (Pitres, 1895, translation in Paradis, 1983, p.48).

From the Pitres' classical paper the most important issues that have been addressed by researchers and clinician are the following: (1) description and explanation of different patterns of recovery; (2) representation of the languages in the brain; (3) assessment of bilingual aphasia; and (4) rehabilitation of bilingual aphasia.

Recovery Patterns

Study of the manifestations of aphasia in bilinguals has served for the elaboration of hypotheses about the cognitive representation and processing of languages and their cerebral organization. Descriptions of verbal behavior of bilingual aphasic

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54041-0

patients reported since the end of the nineteenth century and more extensively over the twentieth century allow for the identification of several patterns of recovery. In extensive surveys of the world literature on aphasia in bilinguals, Michel Paradis (1977, 1983, 1989, 2001) identified the following basic patterns of spontaneous recovery after an injury that caused language impairments: parallel, differential, successive, antagonist, selective, blended recovery, and selective aphasia. Parallel recovery is when both or all languages are recovered simultaneously. Differential recovery refers to cases where one language is recovered much better than the others. Successive recovery is said when the recovery of one language does not begin until another has been maximally recovered. Antagonist recovery occurs when the languages are not concurrently available; only one language is available to the patient, and the language that is recovered first ceases to be available and is replaced by the language subsequently recovered. This pattern may occur recursively and is called alternating antagonism when patients have access to only one language for alternating periods of time. The recovery is selective when patients only recover one of the languages but not the others. Blending recovery occurs when patients inappropriately mix or blend phonological, morphological, syntactic, lexical, and/or semantic features of their languages. Selective aphasia refers to the presence of aphasic symptoms in one language without measurable deficits in the other(s). The incidence of the various recovery patterns based on 138 single cases published from 1843 to 2000 (Paradis, 2004) indicate that parallel recovery is the most common pattern (76%), followed by differential (12.3%), blended (6.5%), selective (4.3%), and antagonistic (0.73%), taking into account that cases of parallel recovery are not often reported.

All these patterns are merely descriptions of patients' verbal behavior in a given situation at a particular time. They are not mutually exclusive and they can be seen as different manifestations on a continuum of time and/or severity. Theoretical explanations have been proposed over the years based on single or multiple factors to account for recovery patterns. Ribot (1881) predicted that the first acquired language, the native language, should be better recovered according to his regression rule which states that the most recent memory traces are the first destroyed and the oldest acquisitions are the most resistant. Pitres (1895) proposed that patients preferentially recover the language that was the most familiar to them at the time of the insult. Pick (1921) suggested that the language most automatized seems to be the first that patients recovered. Minkowsky (1928, 1965) speculated that the recovery responds to the instinctive needs of the patients such as the emotional and affective forces particularly linked to their developmental history. Other authors observed that recovery may be facilitated if the language had been learned in written form (Halpern, 1941; Paradis and Goldblum, 1989). Goldstein (1948) stated that the language first recovered was the most appropriate for the patient's purposes, for example, for helping him/her to communicate in the hospital environment. Lambert and Fillenbaum (1957) and Mastronardi et al. (1991) hypothesized more selective disturbances for coordinate bilinguals, who have acquired each language in a different context than for compound bilingual, who acquired both language in the same context. This hypothesis includes neurological separated structures underlying language for coordinate bilinguals. Albert and Obler (1978) suggested that bilinguals might have different cerebral lateralization for the two languages and from that suggestion it was assumed that nonparallel recovery might result from one language being less lateralized than the other. However, none of the above factors accounts for all the reported cases. Some patients have first recovered their first or second language; some patients first recovered the most familiar language and in some cases, the least familiar; some patients recovered the language of their surroundings and many did not recovered the language of their environment. Recovery seems to be produced by different factors at different times and a theoretical explanation which could account for all the observed recovery patterns is needed. To date the most integrated theory that can account for all the recovery patterns is that proposed by Michel Paradis (2004) reported below.

Paradis' Neurofunctional Model

This model incorporates several hypotheses proposed by Paradis from 1977 to 2004: the Three-Store Hypothesis, the Subsystems Hypothesis, the Activation Threshold Hypothesis, the Direct Access Hypothesis, and the contribution of implicit competence, metalinguistic knowledge, pragmatic capacity, and motivation.

The Three-Store Hypothesis proposes to separate the nonlinguistic cognitive store from the two (or more) language stores of bilinguals. It postulates that bilinguals possess two language subsystems constituted by grammar and lexicon for each language, and one nonlinguistic system that contains conceptual representations which interact with the two linguistic subsystems. The bilingual persons might organize the mental representations of their nonlinguistic system slightly differently in each language. The conceptual system is not language-specific but the meaning of the words and utterances are language-specific because each language specifies what mental representation is included in the meaning of each word or sentence combining features of mental representations in different ways.

The Direct Access Hypothesis proposes that a word or a sentence in either language is perceived directly as a word or a sentence integrating sound and meaning, irrespective of which language it belongs to and without the listener's having to first identify the language affiliation of that word or sentence. The access to the meaning is automatic and the awareness of the language identity of a word or sentence is a metalinguistic phenomenon that occurs after the meaning has been accessed.

The Subsystems Hypothesis proposed an independent neurofunctional language system with two or more subsystems or subsets corresponding to each of the bilingual's languages. The two or more specific subsystems (say, English and Spanish) share the properties of the linguist system whose principles they instantiate along different parameters (rules or forms). Structural distance between two languages can be measured in terms of the number of shared parameters. The two subsystems are subserved by one subset of neural connections for each language while at the same time, because they partake in the general neurofunctional language system, elements of either language can be drawn at any time.

The Activation Threshold Hypothesis proposes that a language or an item of this language (word or morphosyntactic feature) is activated when a sufficient amount of positive neural impulses have reached its neural substrate. The amount of impulses necessary to activate the language or item constitutes its activation threshold. The activation of a language or item requires that this activation exceeds that of the other alternatives that must be simultaneously inhibited. Activation depends on the frequency and recency of use of a particular language or item.

Implicit competence and metalinguistic knowledge constitute two independent systems and two neurofunctional subsystems of communication. These two systems participate in the appropriation of the two languages in bilinguals. If the acquisition is accomplished incidentally by practice, the implicit competence is mainly involved, whereas metalinguistic knowledge is more activated if the appropriation is made consciously and formally.

Motivation and affect are important factors in the acquisition, learning, and use of the first and second languages in bilinguals and contributes to lowering the activation threshold of languages in the same way that frequency and recency of use do.

The Paradis' integrated model allows to explain all the various described patterns of recovery in bilingual aphasia. Parallel impairments can be interpreted as the result of damage in the linguistic neurofunctional system as a whole. Differential, successive, antagonistic, and selective aphasia can be interpreted as the result of damage to one of the language subsystems. Each language, as a subsystem, is susceptible to selective pathological inhibition depending on its activation threshold that can be related to the frequency and recency of use, the acquisition and learning mode (implicit or explicit), and the emotional factors involved in its acquisition and use.

Representation of the Languages in the Brain

The study of the representation of multiple languages in the human brain has been one of the most important issues in the history of research on bilingual aphasia. Several hypotheses have been proposed (for a review see Fabbro, 1999; Paradis, 2001). (1) All languages are represented in the same areas, the classical language areas. This proposal includes several formulations that go from the broad hypothesis suggested by Pitres, participation of the same cortical language centers as in monolinguals, to the more clinically and neurolinguistically based explanation proposed by Paradis (2004), who claimed that the two languages are represented as distinct microanatomical and neurofunctional subsystems located in the same gross anatomical areas. (2) Each language is represented in different areas in the brain. The strongest formulation of this hypothesis is that known as differential lateralization that proposes that the two languages of bilinguals are differently lateralized and one of them is more bilaterally represented. This hypothesis was first suggested by V. Gorlitzer von Mundy (1959/1983), who stated that language centers are originally in both hemispheres, remain in both hemispheres in illiterates but become lateralized in literates due to the instruction and acquisition of unimanual writing skills. Albert and Obler (1978) from an analysis of the literature on case studies and experimental neuropsychology on bilingual aphasia made their famous speculative suggestion that "the right hemisphere …may be dominant for one of the languages of the bilinguals" (p.254) that led to many experimental studies with contradictory results. Many researchers have carried out behavioral studies on cerebral lateralization on language in brain-intact bilinguals, neurological and clinical research on crossed aphasia, but their findings are controversial and constrained by methodological weaknesses and have not advanced our knowledge of the lateralization of language in bilingual speakers (see Hull and Vaid, 2007, 2008; Paradis, 2008). All the evidence gathered to date points to both languages being represented in the language areas of the left hemisphere in the same proportion as in monolinguals. However, many studies on communication disorders in adults with right hemisphere damage confirm that the right hemisphere is crucially involved in the pragmatic aspects of language rather than form or content (Cummins, 2009; Paradis, 1998b). Paradis (1998c) proposed the term dyshyponoia to refer to impairments of the use of linguistic pragmatics produced by right hemisphere damage; e.g., the inability to draw appropriate inferences from the context or from general knowledge, leading to problems in the interpretation of indirect speech acts, metaphors, and in general in the unspoken components of an utterance. In this sense, a greater involvement of the right hemisphere in bilinguals may be necessary to apply pragmatic features when using the appropriate language in certain contextual circumstances. Pragmatics is also necessary to compensate lacunae in implicit linguistic competence.

Neuroimaging Studies of the Bilingual Brain

The advent of noninvasive neuroimaging techniques such as positron emission tomography (PET), functional magnetic resonance imaging, event-related brain potentials, and magnetoencephalography, has permitted the investigation of language organization in bilinguals. From the first PET study by Klein et al. (1994), who used a word repetition task in a group of Canadian bilinguals who were native English speakers and French speakers after age 5 to elucidate whether production in a second language involved the same neural substrates as in the first language, many different studies have been carried out (see for reviews Abutalebi et al., 2001; Vaid, 2008; Vaid and Hull, 2002). To date we have a large amount of puzzling and sometimes contradictory findings from different neuroimaging techniques, different linguistic tasks, and different types of healthy bilingual individuals (see for a review Sebastian et al., 2011). From these results one may derive some patterns: (1) the activation of the left perisylvian area increases with degree of proficiency or implicit linguistic competence in the second language suggesting that brain activity converges toward that of the first language (Chee, 2009); (2) activation of the left prefrontal cortex, anterior cingulate gyri, and basal ganglia increases as fluency in the language decreases, indicating an increased use of controlled processes as additional support to processing the weaker language (Abutalebi and Green, 2007, 2008); (3) activation of

the right temporal lobe increased also in late bilinguals (Dehaene et al., 1997; Perani and Abutalebi, 2005) suggesting the involvement of pragmatic processes to compensate their weaker linguistic competence; (4) activation of parahippocampal gyri associated with declarative memory was observed during the use of the second language. It is important to note that studies using single-word stimuli find no differences between Language 1 and Language 2 cerebral representations, whereas studies that use sentences do (see Paradis, 2004).

The neuroimaging studies of bilingual aphasia patients are scarce and focused on examining the effects of specific language treatment on the representation of language areas during the recovery. Although they are limited to particular language tasks, picture-naming tasks and word semantic judgment task, and to case studies, they provide interesting findings. (1) Improved performance in the treated language was associated with increased activation in language area and in regions associated with control (anterior cingulate cortex, the left caudate, and prefrontal cortex), which form together a whole network with stronger connections for the treated language and with weaker connections for the untreated language. This network is completed by the left basal ganglia and left prefrontal circuitry that may subserve language planning and inhibition (Abutalebi et al., 2009). These results provide neurobiological evidence for the activation threshold theory and for the contribution of metalinguistic competence postulated by Paradis (2004). (2) The improvement of the treated language is accompanied by bilateral activation of the left and the right superior temporal, in frontal (inferior and medial frontal areas) and inferior parietal areas, while the activation pattern of the untreated language remains unchanged (Meinzer et al., 2007). (3) The activation for the weaker language is greater than for the more fluent one and includes both left hemisphere and right hemisphere regions, superior temporal gyrus, postcentral gyrus, supramarginal gyrus, and subinsular lobe, indicating that bilingual patients need to recruit a more distributed network of regions during the processing of the less proficient and used language. There is also a great variability in activation pattern which indicates that less proficient bilinguals engage greater cognitive resources when processing the less used/less proficient language (Sebastian et al., 2012). (4) When the level of proficiency and use is high in both languages, the same cerebral regions are recruited for both languages before and after training. Increasing activations are observed perilesionally and in homologous contralesional areas (Marangolo et al., 2009).

The Assessment of Bilingual Aphasia

Assessment of language proficiency, history and contexts of acquisition, and use of the two or all of multilingual's languages is essential for purposes of diagnosis, research, and treatment. Literature on different recovery pattern has shown that many factors are responsible for parallel or differential recovery such as the history and contexts of acquisition, the history and contexts of premorbid uses, and the structural relationships of the languages. Postlesional proficiency of bilingual aphasics must be assessed with an equivalent instrument in each language which could test phonology, morphology, grammar, lexicon, and semantics so that the results obtained may be validly compared. Different standardized test batteries are available for assessing bilingual aphasia. Most of them are originally constructed in English and then translated into other languages, but it is very important that all languages of a person with aphasia are assessed by means of a cross-linguistically equivalent instrument and not by a mere translation of a standardized test from another language (Paradis, 2004). The criteria of cross-language equivalence must include the cultural appropriateness of items, the equivalence in complexity of syntactic structures rather than the same translated constructions, the selection of phonological minimal pairs which are depending of the structure of each language and the equivalent frequency, and use of the selected words. In order to provide a systematic and cross-linguistically comparable instrument to assess bilingual aphasia, Michel Paradis developed the Bilingual Aphasia Test (BAT) which was designed to be equivalent across the 65 languages in which it is currently available (Paradis, 2011; Paradis and Libben, 1987).

The BAT examines language performance in all four modalities (hearing, speaking, reading, and writing). It is linguistically multidimensional because it explores, for each modality, language performance along three dimensions: (1) linguistic level – phonological, morphological, syntactic, lexical, semantic; (2) linguistic task – comprehension, repetition, judgment, lexical access, propositionizing; and (3) linguistic unit – word, sentence, paragraph. The BAT is composed of three parts. Part A assesses the patient's history of bilingualism and it is devoted to obtaining information about the context of acquisition and use of all the languages acquired by the patients, exploring the patient's linguistic environment at home, education, and work from their childhood to the present. Part B provides information relating to the language background, spontaneous speech, and linguistic competence (comprehension and production) for each of the languages tested. Part C examines bilingual skills in a specific pair of languages and comprises four tasks in each direction: recognition of translation-equivalent words, production of translation-equivalent words, translation of sentences, and grammatical judgments. Within each task, the patients' performance in one language may be compared with their performance in the other.

The Rehabilitation of Bilingual Aphasia

As pointed out by Paradis (2000), the study of aphasia rehabilitation in bilingual subjects is one of the major challenges facing the neurolinguistics of bilingualism in the twenty-first century. There are numerous questions that need to be addressed. In what language should the therapy be performed, in all languages that the patient spoke previously, or in only one language? If it is necessary to perform the therapy in all languages, how should this be done: simultaneously or successively, and why? If one of the languages must be selected for therapy, what criteria should be applied, the native language, the one that was the most fluent premorbidly, the best recovered, the language of the environment? Can the benefits obtained from therapy in one language transfer to the untreated language? If so, on what factors does this transfer depend, the structural distance between

the languages, the age or acquisition, the dominance pre- or postonset, the type of aphasia, the pattern of recovery, or the type of therapy? (Paradis, 1993, 2004).

The number of studies on rehabilitation in bilingual aphasia is limited even though it is increasing since the beginning of the twenty-first century, especially those focused on the effect of treatment in one language on the untreated language(s) (see as examples in Galvez and Hinckley, 2003; Goral et al., 2012; Hinckley, 2003; Kiran and Roberts, 2010; Kohnert, 2004; Miller Amberber, 2012). The differences between them, including variation in the assessment measures, treatment approaches, type and severity of aphasia, proficiency in each of the languages, and acquisition history of participants, make interpretation of results problematic (see for reviews, Faroqi-Shah et al., 2010; Juncos-Rabadán et al., 2002; Roberts, 2008). Notwithstanding the enormous variability among the reported cases, and their methodological limitations, several hypotheses have been proposed from the findings: (1) Chlenov's (1948) hypothesis that therapy should initially be carried out only in one language, the language in which spontaneous recovery typically occurs and which may or may not be the mother tongue, thus avoiding the probable inhibitory effect of therapy in two languages. Only when significant recovery has been achieved in the basic language should treatment be attempted in the other. (2) Transfer from the treated language to untreated language might be affected by several factors such as structural distance between the two languages, age of acquisition, and the level of proficiency. (3) Structural distance is the main factor for transfer when therapy is based on morphology and syntax; however, age of acquisition and the level of proficiency are more important when the therapy is focused on the lexicon. (4) Pragmatic and social factors such as the history of use of a particular language and the language of the environment during the treatment have been proposed to account for the presence and absence of cross-language generalization. (5) No clear trends emerged regarding the potential interaction between these factors and the studies highlight the inherent problem of variability in research on bilingual aphasia therapy.

In the light of the Paradis' neurofunctional model, several processes and strategies have been proposed to apply for treatment of bilingual aphasics (Juncos-Rabadán et al., 2002). Activation, competition, priming, and inhibition can be applied to the therapy of linguistic fragments, levels, or skills of the treated language. For instance, the activation of the lexical unit corresponding to a target word in one of the languages will be facilitated supplying contextual and phonological primes specific for this language and restricting the number of competing alternatives from the other language. If the lesions affect basically implicit memory the focus of the therapy should be on explicit learning using metalinguistic knowledge and strategies such as semantic–conceptual and semantic–syntactic therapy; if the lesions affect explicit memory, the focus will be on implicit learning such as identification and associative priming.

A recent approach to addressing rehabilitation in bilingual aphasia is to use computational modeling to complement our understanding of how language recovery occurs in a bilingual individual with aphasia (Kiran et al., 2012). However, this approach is constrained by the necessity of simplifying models to particular tasks such as naming, by a particular architecture of the computational model, and by the limitation of factors that are considered, for example, age of acquisition and level of proficiency.

Conclusion

Bilingual or multilingual individuals with aphasia recover their languages at different times and to different extents. This recovery pattern depends on several biological and ecological factors. For a better understanding of these factors, more case and group studies – carefully assessed with an equivalent instrument across different languages and administered before and after controlled therapy programs – are needed. Experimental and neuroimaging studies have as challenges for the future to find linguistic tasks that form part of the natural use of language and to use reliable and replicable techniques with comparable subject populations in order to get data that allow valid inferences within a theoretical framework on bilingual aphasia. From these theoretical explanations new strategies and methodologies must be designed to rehabilitate bilingual/multilingual persons with aphasia in order to improve their communicative competence and quality of life.

Bilingual Education: International Perspectives

Abstract

The article deals with the objectives and types of bilingual education, from traditional models such as *immersion*, *submersion*, and *dual language curricula* to current initiatives. Among the goals, assimilation of linguistic minorities, heritage-language maintenance, and linguistic empowerment are prominent. Reasons for the success or failure of various approaches are discussed, and it is shown how controversies and attitudes reflect dominant ideologies. It is argued that evidence from research on bilingualism/multilingualism in general and, in particular, on bilingualism in early childhood underscores the superb human ability to deal with more than one language at a time and, therefore, encourages efforts of implementing bilingual language programs throughout the educational system.

The majority of the world's population knows, speaks, and sometimes even writes in more than one language. Given the human cognitive capacity of managing multiple linguistic systems fairly effortlessly, educational curricula employing two or more languages of instruction, with schools profiting in turn from the linguistic and cultural resources of bilingual and multilingual individuals, should be quite common and find wide acceptance. However, to this day, bilingual or multilingual education is a controversial topic, with positions ranging from active promotion to more or less subtle resistance – the latter often camouflaged by liberal and pluralist rhetoric. While researchers no longer question that children can be raised with and schooled in more than one language without negative consequences for their linguistic, emotional, and cognitive development, prejudice, xenophobia, or simply ignorance raise the stakes for bilingual or multilingual programs. Their fate is intricately linked to attitudes toward bilingualism in general and also toward the languages involved. The European Commission, for instance, encourages European citizens to acquire two languages besides their first language(s), and it celebrates the cultural and linguistic diversity of its community as an added value, sure to guarantee a return on investment within the global market. At the same time, the multitude of immigrant languages and cultures originating from other parts of the globe does not appear to count, and the linguistic competence of children growing up with non-European languages and cultures is dismissed or treated as an obstacle and handicap. As pointed out by Stubbs (1991 (1995: 30)), "there is likely to be an enormous waste: allowing languages already spoken in the home and community to be eroded, whilst starting from scratch to teach other languages in schools and colleges." Even though my contribution can only marginally deal with contradictions and double standards of this kind, they nevertheless form a part of the backdrop for what follows.

After an explication of relevant terminology, an overview of the objectives and major types of bilingual education, such as the 'classics' Immersion, Submersion, Transition, Dual Language/Two Way models, and a recent offspring of immersion, Content and Language Integrated Learning (CLIL), are provided, and some parameters determining their effectiveness are identified. A brief historical sketch, mainly based on developments within the United States, then illustrates how the political climate swings attitudes in favor of or against the goals and types of bilingual education. The final section brings together what we have learned from more than five decades of documentation and assessment of bilingual programs with current research on language acquisition and bilingualism.

Definitions

In a strict sense, for educational programs to qualify as 'bilingual,' the following conditions should be met: (1) at least two languages serve as media of instruction in subjects other than language classes, and (2) bilingualism, biliteracy, and biculturalism are explicit goals and emphatically supported by all stakeholders.

These criteria are not always adhered to by schools and programs claiming the label 'bilingual' for their various efforts in language teaching. Throughout the literature, *bilingual education* is also used in connection with bilingual families raising children with two or more first languages from birth. While my main focus here is on the fate of languages in schools, this article also mentions which findings from the research addressing bilingualism in early childhood and the study of bilingualism and multilingualism in general could be particularly pertinent to bilingual education as well.

For the purpose of this contribution, reference to bilingualism is meant to subsume multilingualism, and *acquisition* and *learning* are employed synonymously. *L1* refers to a child's first language(s), hence includes the simultaneous acquisition of two or more first languages, and *L2* is used as a shorthand expression for any language(s) acquired after age 3–4. Two additional terms need explication because usage is, to some extent, counter-intuitive: *majority* and *minority* (languages). Regardless of actual numbers, *majority* refers to linguistically 'powerful' speakers whose language rights are not in question. Their L1 typically reflects a society's accepted default, the socially *dominant*, and possibly, the constitutionally guaranteed *official* language. For majority children – even though one or two foreign languages, that is, languages not part of the local environment, may be mandatory subjects within their educational system – bilingualism is a matter of choice, in the ideal case a culturally and cognitively enriching experience, and it typically involves other, equally high-status majority

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92044-0

languages. The result is considered *additive*, not *subtractive* (Cummins, 1991; Baker, 2011). This means that becoming bilingual entails no threat to majority children's L1, their sense of identity and their social and cultural networks. Minority children, on the other hand, have no real choice since their L1 competence is irrelevant within a majority-language context. If they are to have a future within the mainstream educational system and beyond, they have to acquire the linguistic currency needed within the majority-dominated symbolic market.

Motivation and Aims of Bilingual Education

Over the past 50 years, bilingual curricula have emerged in many parts of the world (cf the overviews in Baker and Jones, 1998; García, 2009). Alongside globalization and internationalization, the following factors have been conducive to this development: (1) the coexistence of two or more official languages, as in Belgium, Canada, Luxembourg, Northern Italy, and Switzerland; (2) the coexistence of any number of indigenous languages alongside a non-indigenous, former colonial language functioning as a 'neutral' official language, such as English in Ghana and Ethiopia, French in the Ivory Coast, and Portuguese in Mozambique; (3) immigration and dramatic dropout rates of minority-language children in schools originally designed for majority children; and (4) grassroot movements rekindling interest in the revival of ethnic cultures and heritage languages.

Against this general background, three different educational objectives can be identified:

1. assimilation of immigrant and indigenous minority groups into mainstream society;
2. maintenance and development of the first language of minority children (immigrant and indigenous); and
3. linguistic and cultural enrichment and empowerment for any learner, that is, of minority and majority children alike.

Assimilation acknowledges at least a phase of transitional bilingualism. For Skutnabb-Kangas, assimilation reflects a linguistic variant of racism, 'linguicism' (1988 (1995: 40)), since it results in the "dominance of one language at the expense of others," for her a clear violation of linguistic human rights (1988 (1995: 45)). In transitional bilingualism "[l]anguage loss appears to be recommended" (Stubbs, 1991 (1995: 33)), which explains the critical stance taken by most, though not all, linguists (Hayakawa, 1992). For those favoring the second goal, maintenance and further development of children's L1, the following arguments play a particularly prominent role:

1. Children's sense of identity, awareness of their family's cultural roots, and their self-esteem are strengthened.
2. A curriculum with contents taught through their L1 allows minority children to keep in step with majority children as far as school subjects, world knowledge, and – if literalized in the L1 – cultural tools like reading and writing skills are concerned.
3. Language maintenance helps revitalizing minority languages threatened by extinction. This aspect matters particularly from the point of view of indigenous minorities.

The third general objective mentioned above, namely the enrichment and empowerment of all, is very much in line with current insights into cognitive advantages of bilingualism, such as enhanced metalinguistic awareness, theory of mind development, flexibility, executive control, and self-confidence with respect to language learning in general.

Prototypes of Bilingual Education: a Brief Overview

According to Baker (2011) and Baker and Jones (1998), educational policies can be positioned along a continuum from *weak* to *strong*, depending on how seriously and effectively they endorse bilingualism.

Strong Candidates

One intensively studied form of bilingual education consists in the *immersion* of whole classes of majority children in a second language, such as English L1 speakers in French L2 programs in Canada, which may begin in kindergarten (*early immersion*) or later grades (*late immersion*). Teaching in the L2 may be *partial* in the beginning, starting with a small selection of subjects (such as math and geography) or *total*, encompassing all subjects. In the case of *early total immersion*, a shift toward teaching at least some or half of the subjects in the L1 follows in later years. *Maintenance* or *Heritage* programs have also been counted among the strong educational options. Minority children are taught in their L2 and also in their L1 at least 50% of the time. Successful programs have led to the revitalization of Navajo in the United States, of Catalan, Gaelic, Finnish, Welsh, Ladinian, and other minority languages and dialects in Europe, of Maori in New Zealand, of immigrant languages in Israel, and of aboriginal languages in Australia.

Two Way or *Dual Language* education teaches through both minority and majority languages. Ideally, balanced numbers of native speakers of each language share a classroom, as in English–Spanish schools or in tandem with English and other languages in North American contexts. Languages employed may alternate, either by subject, day, or some other consistent principle. Baker (1993 (1995)) describes Welsh–English programs where native speakers of both, aged 11–16, are jointly taught in Welsh for at least 70% of the curriculum. Because equal attention is given to the languages, cultures, and speakers involved, *Dual Language* curricula have also been implemented as part of the peace process in ethnic conflict zones (Tankersley, 2001).

Instruction via two or more parallel languages, sometimes offering different choices of language pairs, is an important characteristic of *International Schools* and *European Schools*. The languages to choose from are, in most cases, high-status majority languages. Predominantly enrolled are children of internationally mobile families (e.g., diplomats, academics, members of international companies) and of local socioeconomic and intellectual elites.

With its explicit double focus on subject content and medium of instruction, *Content and Language Integrated Learning* (CLIL) has turned into a very popular European immersion variant over the past 20 years (cf Coyle et al., 2010). It deserves a place among the strong forms of bilingual

education, even though it may also be implemented on a small scale, that is, by individual teachers and within the microcosm of specific subjects classes in schools that don't offer a long-term or in-depth bilingual program. CLIL pedagogy stimulates authentic L2 communication among students in task-based interactions, and explicitly acknowledges the bilingual potential available in the classroom. Thus, the purist dogma of keeping languages strictly separate is replaced by a communicative style welcoming code-switching, which makes CLIL approaches very congenial to the goal of fostering the resourcefulness of bilingual speakers.

Weak Candidates

A 'sink or swim' educational policy known as *submersion* is the most widespread way of schooling individual minority children, both immigrant and indigenous. The child is placed in mainstream classrooms, sometimes assisted by additional instruction in the majority language, in the North American context called *withdrawal* or *pull-out* classes. Classes containing only minority children, while superficially looking very much like the immersion of majority children (often referred to as *structured* immersion) differ in the outcome, a point I return to in the following section.

An equally 'weak' form in terms of results and – by definition – goals consists in *transitional* models, which start by teaching in the minority child's L1, but as soon as possible, move over to instruction via L2.

Further Options along the Strong–Weak Continuum

Throughout childhood and beyond, language learners may well experience a mix of different teaching strategies and types of exposure to new languages or mother tongue instruction. Language policies aiming at mainstreaming may well tolerate bilingualism as a personal privilege, confining the 'other' languages to the invisible, private domain (cf also Stubbs, 1991).

Without support of minority languages at school, L1 instruction may be sought in other ways. This was, and sometimes still is, the case for children and grandchildren of the 'Gastarbeiter' (immigrant worker, 'guest worker') families, who first came to Germany about 50 years ago. Consulates of countries of origin, parental initiatives, and religious organizations may provide L1 classes in addition to submersion in the majority language.

Apart from motivation and long-term goals, implementation of the types of bilingual education mentioned here may differ significantly in conceptual, organizational, and administrative detail (cf Mehisto, 2012). Since terminology may differ too, it is not always easy to recognize where on the weak–strong continuum individual programs should be placed. In many countries, the French and English expression *immersion* has been borrowed as a superordinate term for what, especially in preschool settings, is considered to be the ideal assimilatory and submersive strategy for dealing with large groups of young minority children and, independently of any migration background, with children from socioeconomically disadvantaged milieus.

Additionally, there has been a rapidly increasing demand on the part of middle-class parents requesting foreign language programs for daycare centers and kindergartens. In response to this pressure, more and more preschool institutions offer various foreign language or second language activities, from an occasional, minimal encounter in the form of songs, games, and communicative routines to total immersion programs. Sometimes, bilingual kindergartens emulate the *one person–one language strategy* employed by bilingual families, with teachers, ideally native speakers, strictly requested to stick to only one language. Quite understandably, many middle-class bilingual parents who have consciously decided to raise their children with two simultaneous first languages are very eager to find family–external support for a non-dominant language spoken at home. The European Community also explicitly encourages parents from monolingual families to expose their children to additional (especially European) languages as a key to success in a globalized world (cf www.piccolingo.com). What is not often communicated (or simply not known), however, is that an offer of isolated lexical items (as in picture naming), or even recurrent songs and rhymes, while fun and harmless, does not provide effective keys for cracking the many codes of a new language unless these activities are supported by authentic communicative experience and guaranteed continuity, ideally within the educational system.

Findings and Challenges

In his overview of European initiatives Baetens Beardsmore (1993 (1995: 147)) concludes that "[n]o single model of bilingual education is universally applicable and no single existing model should be transplanted to a totally different context." He also cautions against unrealistic expectations: "The message to the educational planner, then, is not to expect bilingual education to produce native-like competence in two languages if the contextual variables do not allow for this to develop" (Baetens Beardsmore, 1993 (1995:148)). This last point stresses the basic unfairness of expecting an outcome simply impossible under unfavorable circumstances, such as gaps and a reduced spectrum of registers and styles in the input.

The weak–strong metaphor proposed in the literature and employed above is based on the relative success of forms of bilingual education, especially in the light of their aspirations. One of the most important findings emerging from the pioneering Canadian immersion experience, justifying its position at the 'strong' pole, was that L1 English majority children enrolled in French L2 immersion programs did not lag behind control groups of monolingual native speakers of English in their L1 proficiency. This means that in the case of majority speakers, length of exposure to L1-taught classes did not seem to matter. Neither did teaching science or math through children's incipient L2 interfere with their academic progress in these subjects. With respect to their emerging L2 proficiency, best results were achieved in early total immersion.

Maintenance programs, with instruction in both L1 and L2, also proved successful, but while they support children's L1 and ethnic identity, they may also segregate them from their majority peers. This is where Two Way/Dual Language schools have the clear advantage of bringing together relatively balanced numbers of students from both linguistic and cultural backgrounds and by giving equal status and rights to both

languages. Since Two Way/Dual Language schools typically rely on parental involvement and on the support of their communities, they offer – quite literally – a 'common ground' for families as well.

These various positive findings are in stark contrast with the results for learners participating in the other, hence 'weaker' group. To this day, it is puzzling that the average minority child performs below the norm in submersion classes and responds less well to what superficially look like challenges identical to those mastered by majority children, namely the simultaneous exposure to a new language and new contents, and that they do not even perform well in transition classes. To make things worse: it turned out that minority children underperformed not just in their L2 but also in their L1. To be sure, there are many individuals from minority cultures who manage to thrive even under submersion conditions, and who consequently believe that everybody else should be able to succeed as well, and that any special language-related treatment of minorities is some new racism in disguise (for instance Hayakawa, 1992). All in all, available evidence allowed the conclusion that simply more majority language instruction did not pay off, at least not to the extent expected, and not for the average minority child.

Cummins (1991) and in many other publications explains this majority–minority achievement discrepancy by proposing that cognitive benefits of bilingualism could only emerge once both languages had reached a certain *threshold* or level of proficiency, and that an advanced level of L1 before L2 exposure was a good predictor for successful L2 acquisition as well, an assumption known as the *interdependence hypothesis*. That a relatively advanced L1 should prove more resistant to the growing pressure from a prestigious L2, and that skills and concepts already mastered in L1, including literacy-related expertise, should be transferrable from L1 to L2, sounded entirely reasonable and has had a huge impact on pedagogical studies. World knowledge acquired via L1 as well as domain-general cognitive skills relating to memory organization, problem solving, inference, etc. should remain accessible. However, the attempt to identify concrete linguistic system properties which could offer themselves as a basis for transfer, quickly leads to an impasse since in many cases the result would hardly be helpful and would have to be 'undone' again. To mention just one concrete example, an L1 without articles (such as Russian or Turkish) does not offer itself as a fruitful model for a language which requires them (e.g., French, English, and German). In this case, ignoring L2 articles results in negative transfer (interference). As we know from older L2 learners of any target language, negative transfer due to solidly entrenched L1 properties which represents a problem rather than a solution.

One important overall message to be gained from years of studying the effectiveness of bilingual education is that positive effects require time. While learners very quickly (within 2–3 years) pick up elementary communicative routines, which Cummins (1991) refers to as *Basic Interpersonal Communicative Skills* (BICS), decontextualized registers relying heavily on written styles (*Cognitive/Academic Language Proficiency*, CALP) require more time (5–7 years; numbers proposed differ across studies). As argued by Baker (2011), BICS and CALP cannot be distinguished in a clear-cut manner. From a linguistic point of view, the distinction underestimates the inferential know-how and the intention-reading needed for the interpretation of informal speech. That is, in terms of their pragmatics, BICS are far from simple. One additional drawback Baker stresses is that "[s]uch terms may be used to label and stereotype students, especially if BICS are seen as inferior to CALP […]" (2011: 171). Learners who have never been exposed to academically oriented varieties simply have no reason to even miss them.

One is forced to conclude that the outcome of bilingual education depends on many interacting variables, some of them poorly understood to this day. What complicates matters is that developmental L1 norms are available for only a tiny fraction of the 6000 to 7000 existing languages known today. In the case of L2 development, there are hardly any norms based on large samples taking into account the age of onset and the duration of exposure. This also means that most assessments of bilingual children's competence is based on L1 norms, which makes poorer results highly predictable and raises, once more, questions of fairness.

One particularly relevant variable stressed in virtually all evaluations concerns the teachers and their professional competence, commitment, and, ideally, their function as convincing role models. For some researchers, the involvement of bilingual teachers is an absolute essential. Skutnabb-Kangas goes as far as to suggest that "[a] teacher, monolingual in L2, can never be a really good L2 teacher! A good L2 teacher knows both languages" (1988 (1995: 51)). While this is a desirable goal in general, providing all minorities with teachers who also know their L1 may well be too much to ask in the case of linguistically heterogeneous classrooms with children from many different first languages. Not only is the spectrum of first languages in contact within the same classroom a daunting pedagogical and linguistic challenge. Children born into families with an immigrant history may have most likely been exposed to some linguistic variety at home which already underwent significant change due to loss of close contact with a pre-immigration dialect of origin and due to intensive contact with new languages. Polinsky and Kagan (2007) argue that it is this variety that should be used as an appropriate and fair *baseline* against which a learner's competence ought to be compared, not some idealized norm that he or she has never been exposed to. It is crucial therefore that teachers involved in L1 instruction have a rough idea at least of how the variety he or she takes to be an appropriate target, differs from the heritage language internalized by learners. Polinsky and Kagan (2007: 374) describe what typically happens when even highly motivated heritage speakers who had shifted to some L2 early on, attempt to build on their rudimentary L1 competence: "[…] the heritage learner's competence is always suspect, and both instructors and curriculum designers take stock only of their deficiencies" and "[t]he problem is acerbated in cases where language instructors are biased against the language variety that served as the home language" (Polinsky and Kagan, 2007).

The question of which variety to pick as language of instruction in a bilingual educational setting and how to make sure that individual learners can relate what he/she knows to the instructional medium is far from trivial. It raises the question of how one can do justice to all children's linguistic rights in the absence of bilingual curricula and material, appropriate tests, and competent bilingual teachers for each and all

language combinations already spoken by children in schools and preschools all over the world. Educational contexts involving learners with diverse language backgrounds and differing degrees of proficiency in their heritage languages therefore pose a tremendous challenge for any educational system, but it also holds a great promise. In the light of this diversity it would seem sensible to start with a strong focus on a general subject, *Language* or *Language awareness*, as an appropriate forum where all learners could be encouraged to reflect on their linguistic repertoires and, in particular, on their bilingual resourcefulness.

Bilingualism and Education: a Brief Historical Excursion

In their overview of the history of bilingual education in the United States, Baker and Jones (1998) (see also Baker, 2011; Lyons, 1990) distinguish four overlapping periods characterized by what they call (1) permissiveness, (2) restrictiveness, (3) opportunity, and (4) dismissal. Before World War I, tolerance of linguistic diversity prevailed. Many ethnic communities taught children in languages other than English. But the Nationality Act of 1906 required immigrants to learn English in order to become naturalized citizens. World War I and new immigration waves led to calls for assimilation and Americanization, a development strongly reinforced by World War II, and to the restriction of public school instruction in languages other than English. This attitude relaxed in the wake of the Civil Rights and Equal Education movements in the 1960s and a growing interest in ethnic values and traditions. In addition, the persisting academic failure of children considered *Limited English Proficient Children* raised the issue of equal opportunity and led to calls for compensatory measures. Courts mandated bilingual education for minorities, and amendments to Education Acts made federal funds available. A next period, starting in the 1980s, took a turn in favor of submersion and transition programs, vigorously supported by pressure groups such as US English, English First, or English for the Children and, most recently, No Child Left Behind (see respective websites). Currently, yearly assessments are supposed to guarantee that schools and teachers make sure that students move into mainstream classes as soon as possible. As a consequence, L1 maintenance is typically dismissed.

The overall history of bilingual education for both immigrants and indigenous minorities in North America clearly reveals an intricate connection between ideology, power, and educational policy. Without doubt, conservative forces anywhere will continue to consider bilingualism in the public domain "a costly and confusing bureaucratic nightmare" (Hayakawa, 1992: 44) and a source of political disloyalty and destabilization. While nobody seriously objects to teaching high-status foreign languages to elites, bilingual education involving low-status minority languages is seen as the cause of scholastic underachievement. It may be a small comfort to supporters of bilingual (maintenance) programs that *Dual Language education/Two Way immersion* programs continue gaining recognition. Not only do they represent 'the antithesis of assimilation' (Baker, 2011: 229), but they also demonstrate that empowerment of minority and majority children is possible. It will be interesting to observe how the European commitment to 'unity in diversity' and Europe's vision of sustainable multilingualism and, moreover, a proclaimed 'consolidating' factor will fare in the future. The attempt to motivate children and adults to go for the languages of the smaller European countries is also meant to soothe concerns within these countries that their languages and cultures may be 'assimilated' as well and hence marginalized and wiped out in the long run. Given the rate at which threatened language die out, this expectation is not unrealistic. At the same time it can be shown that interest in the revival and survival of ethnic languages can be rekindled through well-thought-out educational planning in which strong bilingual programs play an important role.

Bilingual Resilience

In the past, supporters of bilingual education have had to contend not just with those who fear that multilingualism and cultural diversity lead to societal disintegration and social unrest, but also with those who, in principle, value the mastery of additional languages, especially those carrying prestige, as a cultural ideal and an important cognitive asset but who are nevertheless concerned about negative consequences for young children's cognitive, linguistic, and emotional development. Hence, in addition to concerns about an early shift to some majority language and the subsequent deterioration and attrition of minority languages, there is the more general question of an optimal time of first exposure, regardless of status differences. While myths fed by ideology and xenophobia are hard to eradicate, anxieties about children's ability to cope with coexisting languages can take comfort from decades of experience with bilingual education, and, in addition from our current understanding of bilingualism in general and in early childhood. Psycholinguistic experiments involving both children and adults have by now revealed a number of advantages of bilingualism in comparison with monolinguals with respect to executive control, metalinguistic awareness, divergent thinking, and self-esteem, to mention but a few (cf Bialystok et al., 2004); but some drawbacks can be identified as well, for instance delayed lexical access and somewhat slowed-down lexical decisions (cf de Bot et al., 2005; Grosjean, 2008).

Bilingualism is a natural state of the human brain, and due to its demands on self-monitoring and control – after all, the language not needed at any particular moment has to be inhibited – it keeps us mentally agile and appears to delay cognitive aging (cf Bialystok et al., 2004). Nevertheless, the long-term coexistence of more than one linguistic system within a single head hardly remains without consequences. Grosjean (2008: 9; see also 1982) criticizes what he calls a 'fractional view' according to which bilinguals are expected to behave like two monolinguals in one body and to keep their languages neatly apart. A more realistic view of bilingualism acknowledges the existence of tight cross-linguistic networks, with coactivation and competition a natural result of the coexistence of different linguistic systems within a single head. Perfectly balanced repertoires are unlikely, especially in bilinguals employing their languages according to some

division-of-labor principle, aligning their languages with different contexts, topics, or functions. Cross-linguistic coactivation and priming enhance the smooth and fluent transitions between languages known as *code switching* (cf Bullock and Toribio, 2009; Gardner-Chloros, 2009). Of course, what starts as formally and functionally highly skilled performance due to coactivation may eventually lead to a convergence of subsystems and, hence, to individual language change. The result would be some new, hybrid system, hopefully acquired as an L1 or an L2 by future generations.

Finally, it is instructive to look at very early bilingualism, especially at children growing up with two simultaneous first languages (cf Genesee and Nicoladis, 2007; Meisel, 2004). Since it is unlikely that their input is evenly distributed across different languages, we would not expect children to come up with perfectly balanced and equivalent systems. Longitudinal case studies show that children exposed to simultaneous first languages are very good at constructing parallel albeit separate representation systems. Evidence comes, for instance, from the asynchronic development of grammatical subsystems, with different languages in the lead for specific subsystems (Tracy and Gawlitzek-Maiwald, 2005).

Clearly, children are not thrown off track by the very presence of two (or more) linguistic systems in their environment, even though language pairs may make it easier or more difficult for them, or for learners of any age, to work out similarities and differences. It must also be recognized, though, that not all children exposed to two languages from birth will embrace them actively, speak them equally fluently, or maintain them throughout their lifetime. Whatever happens in the long run will depend both on opportunity (provided by the environment) and relevance (possibly a very personal decision). Crucially, and relevant within the current context, early bilingualism is living proof that there is no need for one system to reach a certain threshold before another is allowed to enter the stage. The ability of preschool children to cope with more than one language at a time is also stressed in recent studies of early L2 exposure, that is, of cases where the encounter with a second language takes place around age 3 to 4 within kindergarten settings (cf Rothweiler, 2006).

The relevance of all these findings to the topic of bilingual education should be clear. Bilingualism from birth and the early successive acquisition of a second language show that the cognitive and emotional capacity for handling multiple linguistic systems simultaneously exists from early on. On the basis of what we know about bilingual competence and performance, that is, about the cross-linguistic coactivation of resources in adults and in children alike, we should be able to develop a more appreciative perspective of what learners can achieve in bilingual education programs.

Conclusion

There is a vast body of publications on bilingual education. This short overview could not even begin to do justice to the overall spectrum of approaches. The topic is naturally complex because language and language behavior are complex, and because bilingual education involves a multitude of variables, not all of them well understood. Nevertheless, there is enough evidence to support the conclusion that bilingual education in the strict sense, as presented in the first section works, if given a fair chance. Whether one wants it to work, given its ambitious goal of sustaining bilingualism, biliteracy, and biculturalism, is an entirely different matter. The fact that bilingual education, in particular for minority children, still has a questionable reputation is remarkable and means that it is still not appreciated that "[b]ilingual education, when effectively implemented, is not the cause of underachievement; rather it is the cure" (Baker, 2011: 201).

In the past and sometimes well into the present, schools have prohibited and punished the use of minority languages on their grounds (Grosjean, 1982: 27ff). What we should have learned from bilingual education programs is that banning or ignoring resources children already bring with them to schools is not just wasteful and unfair but also counterproductive. Bilingual education can be much more than an educational objective or a gateway for careers in a tightly interconnected world. If done well, it explicitly allows all children to be proud and confident of what they know and to build on the natural fascination of young learners with language-related puzzles. Finally, it is to be hoped that more and more bilingual children grow into adults willing to cast their votes – quite literally, and in whatever language it is called for – in favor of high-quality education welcoming all languages and enriching their speakers.

Binary Response Models and Logistic Regression

Abstract

The focus of this article is on regression models for a binary response. In most fields of application, logistic regression has become the standard method for relating a binary response to a set of covariates. In this article the main features of logistic regression are described and some aspects of interpretation of logistic regression are illustrated with an example. The logistic regression model is first introduced for the simple case where there is only a single predictor variable. This model is compared and contrasted with the classical linear regression model. Later the generalizations to more than one predictor variable are considered. A major emphasis of this article is placed on how logistic regression is used in practice and how the logistic regression coefficients should be interpreted. An example, based on data from the US General Social Survey, is used to illustrate and reinforce the main concepts. Finally, three important extensions of standard logistic regression are briefly reviewed: conditional logistic regression, exact logistic regression, and logistic regression for clustered data.

This article describes regression models for the relationship between a binary response variable (e.g., 'success' or 'failure') and a set of predictor variables. Among the many binary response models that have been proposed in the statistical literature, logistic regression has become the standard model for analyzing the effects of a set of predictor variables; logistic regression is ubiquitous in most fields. In common with linear regression (e.g., *see* Linear Hypothesis: Regression (Basics)), the primary objective of logistic regression is to model the mean of the response variable, given a set of predictor variables. However, what distinguishes logistic regression from linear regression is that the response variable is binary rather than continuous in nature. This has a number of consequences for modeling the mean of the response variable. In this article the main features of logistic regression are described and some aspects of interpretation of logistic regression are illustrated with an example.

Introduction to Binary Response Models

In this section, we introduce some notation and consider regression models for a binary response variable. Let Y denote a binary response variable, that is, a discrete response variable having only two categories, for convenience often referred to as 'success' or 'failure.' For example, Y might indicate an individual's political party preference (Democrat or Republican, in the United States), an individual's opinion on the death penalty (favor or oppose), or an individual's self-reported happiness (happy or unhappy). Denoting the two possible outcomes for Y by 0 and 1, the probability distribution of the response variable is the Bernoulli distribution, with $\Pr(Y=1)=\pi$ (and, correspondingly, $\Pr(Y=0)=1-\pi$). The primary goal is to describe the effect on π of changes in a set of predictor variables. For ease of exposition, we will first consider the simple case where there is only a single predictor variable, x. Generalizations to more than one predictor variable will be considered later in the article.

Given that the main analytic goal is to investigate the relationship between π and x, there are a number of alternative binary response models that can be considered. Recall that with a binary response, the mean of Y is $\pi=\Pr(Y=1)$, i.e., the mean of Y is simply the probability that Y takes on the value 1. Since linear models (e.g., *see* Linear Hypothesis: Regression (Basics); Analysis of Variance and Generalized Linear Models) play such an important and dominant role in applied statistics, it may at first seem natural to assume a linear model relating the mean of Y to x,

$$E(Y|x) = \pi = \beta_0 + \beta_1 x \qquad [1]$$

However, this linear model for the probabilities has one obvious difficulty. Expressing π as a linear function violates the restriction that probabilities must lie within the range from 0 to 1, unless constraints are placed on x or on β_0 and β_1. That is, for sufficiently large or small values of x (when $\beta_1 \neq 0$), the linear model given by eqn [1] will yield predicted probabilities outside of the range from 0 to 1. A further difficulty with the linear model for the probabilities is that we often expect there to be a nonlinear relationship between π and x. For example, a 0.2-unit increase in π might be considered more 'extreme' when $\pi=0.1$ than when $\pi=0.5$. In terms of ratios, the change from $\pi=0.1$ to $\pi=0.3$ represents a threefold (0.3/0.1) or 200% increase, whereas the change from $\pi=0.5$ to $\pi=0.7$ represents only a 40% (or 0.7/0.5) increase. In a sense, the units of measurement for a probability or proportion are often not considered to be constant over the range from 0 to 1. The linear probability model given by eqn [1] simply does not take this into consideration when relating π to x.

Because it is more natural to compare values of π in *relative* rather than *absolute* terms, this suggests fitting a linear model relating the logarithm of π to x

$$\log(\pi) = \beta_0 + \beta_1 x \qquad [2]$$

The model given by eqn [2] is often referred to as 'relative risk' regression. It can be easily shown that β_1 has interpretation as the log *relative risk* (associated with a unit increase in x). The relative risk is defined as the ratio of the probability of success ($Y=1$) for a single unit increase in x. For example, when the predictor variable x is dichotomous, taking values of 0 and 1 representing the absence ($x=0$) or presence ($x=1$) of some factor, β_1 has interpretation as the *difference* between the log of the probability of success ($Y=1$) when the factor is present

$(x=1)$ and the log of the probability of success when the factor is absent $(x=0)$, $\beta_1 = \log\{\pi(x=1)\} - \log\{\pi(x=0)\} = \log\left\{\frac{\pi(x=1)}{\pi(x=0)}\right\}$, where $\pi(x=1)$ and $\pi(x=0)$ denote the respective success probabilities (and recall from the rules of logarithms that $\log(a/b) = \log(a) - \log(b)$). Therefore, e^{β_1} has interpretation as the *ratio* of the probability of success when the factor is present $(x=1)$ to the probability of success when the factor is absent $(x=0)$, $e^{\beta_1} = \frac{\pi(x=1)}{\pi(x=0)}$. Relative risks are often considered the preferred measures of association in prospective studies, especially when the binary response of interest is common. In particular, many empirical researchers prefer relative risks because they find them to be simple and intuitively interpretable. However, the relative risk regression model given by eqn [2] shares some of the structural issues associated with the linear probability model. Although the predicted probabilities given by $\pi = e^{\beta_0+\beta_1 x}$ cannot be negative, they can still exceed one for sufficiently large or small values of x (when $\beta_1 \neq 0$).

To circumvent the aforementioned difficulty, alternative nonlinear transformations can be applied to π where the constraints on the predicted probabilities are automatically satisfied. In particular, a transformation of π, say $g(\pi)$, can be chosen so that it maps the range of π from $(0, 1)$ to $(-\infty, \infty)$. Since there are many possible transformations, $g(\pi)$, that achieve this goal, this leads to an extensive choice of models that are all of the form

$$g(\pi) = \beta_0 + \beta_1 x \qquad [3]$$

and where the transformed probabilities are related linearly to x. However, the most commonly used in practice are

1. logit or logistic function: $g(\pi) = \log[\pi/(1-\pi)]$;
2. probit or inverse normal function: $g(\pi) = \Phi^{-1}(\pi)$, where Φ is the standardized Gaussian cumulative distribution function; and
3. complementary log–log function: $g(\pi) = \log[-\log(1-\pi)]$.

We note that all of these transformations are very closely related when $0.2 < \pi < 0.8$, and in a sense only differ in the degree of 'tail-stretching' outside of this range. Indeed, for most practical purposes it is not possible to discriminate between a data analysis that is based on, for example, the logit and probit functions. To discriminate empirically between probit and logistic regression would, in general, require very large numbers of observations. However, the logit function does have a number of distinct advantages over the probit and complementary log–log functions that probably account for its more widespread use in practice. Later in this article we will consider some of the advantages of the logit function.

Logistic Regression

When the transformed probabilities are related linearly to x by the logit function,

$$\log[\pi/(1-\pi)] = \beta_0 + \beta_1 x \qquad [4]$$

this is known as the *logistic regression* model. Recall that if π is the probability of success, then $\frac{\pi}{1-\pi}$ is known as the *odds* of success; the latter term will be familiar to readers belonging to the gambling fraternity. For example, if the probability of success is 0.8 then the odds of success is 4 (or 0.8/0.2) to 1. That is, the probability of success is 4 times as large as the probability of failure. Thus, the logistic regression model assumes a linear relationship between the log odds (of success) and x. Note that this simple model can be expressed equivalently in terms of π,

$$\pi = \frac{\exp(\beta_0 + \beta_1 x)}{1 + \exp(\beta_0 + \beta_1 x)} \qquad [5]$$

While the latter expression may appear to be somewhat more daunting, we simply wish to emphasize that eqns [4] and [5] are completely equivalent ways of expressing the logistic regression model. Expression [4] describes how the log odds, $\log\left(\frac{\pi}{1-\pi}\right)$, has a linear or straight-line relationship with x. Expression [5], on the other hand, describes how π has an S-shaped relationship with increasing values of $\beta_1 x$; although, in general, this relationship is approximately linear within the range $0.2 < \pi < 0.8$ (see **Figure 1** for a plot of π versus x when $\beta_0 = 0.5$ and $\beta_1 = 0.9$). Observe that the expression on the right of eqn [5] cannot yield a value that is either negative or greater than 1. That is, the logistic transformation ensures that the predicted probabilities are restricted to the range from 0 to 1. Finally, note that

$$1 - \pi = \frac{1}{1 + \exp(\beta_0 + \beta_1 x)}$$

so that the odds, $\frac{\pi}{1-\pi}$, is simply $\exp(\beta_0 + \beta_1 x)$, and the log odds can be expressed as $l = l(\pi) = \log\left(\frac{\pi}{1-\pi}\right) = \beta_0 + \beta_1 x$.

Interpretation of Logistic Regression Coefficients

Next we consider the interpretation of the logistic regression coefficients, β_0 and β_1, in eqn [4]. In simple linear regression recall that the interpretation of the slope of the regression is in terms of changes in the mean of Y for a single unit change in x. Similarly, the logistic regression slope, β_1, in eqn [4] has interpretation as the change in the log odds (of success) for a unit change in x. Equivalently, a unit change in x increases or decreases the odds of success *multiplicatively* by a factor of $\exp(\beta_1)$. Also, recall that the intercept in simple linear regression has interpretation as the mean value of the response variable when x is equal to zero. Similarly, the logistic regression intercept, β_0, in eqn [4] has interpretation as the log odds (of success) when $x = 0$; alternatively, if we exploit the expression on the right of eqn [5], $\frac{\exp(\beta_0)}{1+\exp(\beta_0)}$ is the probability of success when $x = 0$. Although eqn [5] can be used to back-transform from the logit scale to the probability scale, we note that it is not possible to back-transform the regression slope, β_1, to the probability scale. This is due to the fact that a constant difference on the logit scale does not translate to a constant difference on the probability scale. For example, a single unit change in the log odds, say from 0 to 1, corresponds to a risk difference of 0.23 (or $\frac{e^1}{1+e^1} - \frac{e^0}{1+e^0} = 0.73 - 0.50$); in contrast, a single unit change in the log odds from 2 to 3 corresponds to a risk difference of 0.07 (or $\frac{e^3}{1+e^3} - \frac{e^2}{1+e^2} = 0.95 - 0.88$).

For the special case where the predictor variable x is dichotomous, taking values of 0 and 1, the logistic regression slope, β_1, has a simple and very attractive interpretation. Consider the two possible values for π when $x = 0$ and $x = 1$,

$$\pi(x = 0) = \frac{\exp(\beta_0)}{1 + \exp(\beta_0)}$$

(obtained by plugging-in or substituting the value 0 for x in the expression on the right of eqn [5]), and

$$\pi(x = 1) = \frac{\exp(\beta_0 + \beta_1)}{1 + \exp(\beta_0 + \beta_1)}$$

(similarly obtained by plugging-in the value 1 for x in the expression on the right of eqn [5]). Then, we can construct a 2×2 table of the cross-classification of Y and x (see **Figure 2**). Notice that the odds, $\pi/(1 - \pi)$, has a very simple expression, $e^{\beta_0+\beta_1 x}$, and the log odds is just the linear predictor, $\beta_0 + \beta_1 x$. Thus it follows that the log of the odds ratio (or cross-product ratio) in this 2×2 table is equal to β_1, i.e.,

$$\begin{aligned}\log\,(\text{odds ratio}) &= \log\left\{\frac{\pi(x = 1) \times [1 - \pi(x = 0)]}{\pi(x = 0) \times [1 - \pi(x = 1)]}\right\} \\ &= l(x = 1) - l(x = 0) = (\beta_0 + \beta_1) - \beta_0 \\ &= \beta_1.\end{aligned}$$

Thus, $\exp(\beta_1)$ has interpretation as the odds ratio of the response for the two possible values of the predictor variable.

The odds ratio has many appealing properties that probably account for the widespread adoption of the logistic function (and, hence, logistic regression) over other functions such as the probit or complementary log–log functions. First, note that the odds ratio does not change when rows and columns of the 2×2 table are interchanged. This implies that it is not necessary to distinguish which variable is the response and predictor variable in order to estimate the odds ratio. Furthermore, a very appealing feature of logistic regression is that the odds ratio, $\exp(\beta_1)$, is equally valid whether the study design is prospective, cross-sectional, or retrospective; indeed, this property of the odds ratio holds for arbitrary x (e.g., a predictor variable x that is nondichotomous or quantitative). That is, logistic regression provides an estimate of the same association between Y and x regardless of whether we (1) randomly sample individuals having $x = 0$ and $x = 1$ and subsequently classify them according to whether $Y = 1$ or $Y = 0$ (prospective design); or (2) randomly sample individuals from a population and cross-classify them according to whether $x = 0$ or $x = 1$ and whether $Y = 1$ or $Y = 0$ (cross-sectional design); or (3) randomly sample individuals having $Y = 0$ and $Y = 1$ and subsequently classify them according to whether $x = 1$ or $x = 0$ (retrospective or case-control design). The case-control design is popular in epidemiological studies when the outcome Y is rare, and the other designs are impractical. In all three study designs logistic regression provides an estimate of the same association between Y and x. We note that the odds ratio is probably the only measure of association that has this property; although the *relative risk* is considered by many to be the preferred measure of association due to its simple and intuitive interpretation, it cannot be estimated from retrospective study designs.

Figure 2 Probabilities of success and failure for logistic regression of Y on x.

Finally, in medical studies where Y typically denotes the presence or absence of a disease or disorder, the odds ratio is often interpreted as an approximation to the *relative risk* of disease. The relative risk of disease is simply the ratio of the probability of disease ($Y=1$) when a risk factor is present ($x=1$) to the probability of disease when a risk factor is absent ($x=0$), $\frac{\pi(x=1)}{\pi(x=0)}$. When the probability of disease is rare, and π is reasonably close to 0 in both of the risk groups (often known as the 'rare disease' assumption), the odds ratio provides a close approximation to the relative risk. Retrospective designs (case (3) above) are especially common in health and medical studies where the possible outcomes of interest are very rare. Although the relative risk cannot be estimated from a retrospective study, the odds ratio can be used to provide an approximation to the relative risk. However, extra care is necessary when interpreting the odds ratio as an approximation to the relative risk in prospective studies. In many prospective studies the binary event is relatively common (say greater than 10%) and the 'rare disease' assumption no longer holds; in these settings, the odds ratio can be a very poor and unreliable approximation to the relative risk and should not be given such an interpretation.

Multiple Logistic Regression

So far, we have only considered the simple case where there is a single predictor x. Next, we consider the extensions of eqns [4] and [5] to the case where there are two or more predictors. When there are many predictor variables, the logistic regression model becomes,

$$\log\left[\pi/(1-\pi)\right] = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_p x_p \qquad [6]$$

where $x_1, x_2, \ldots, x_p$ are the outcomes of p predictor variables. Note that $x_1, x_2, \ldots, x_p$ may represent p distinct predictor variables; alternatively, they may represent q distinct predictor variables (where $q<p$) in addition to a subset of interactions among the predictors. The logistic regression coefficients in eqn [6] have the following interpretations. The logistic regression intercept, β_0, now has interpretation as the log odds (of success) when all predictor variables assume the value zero, i.e., when $x_1=x_2=\cdots=x_p=0$. Alternatively, $\frac{\exp(\beta_0)}{1+\exp(\beta_0)}$ is the probability of success when $x_1=x_2=\cdots=x_p=0$. Each of the logistic regression slopes, β_k (for $k=1, \ldots, p$), has interpretation as the change in the log odds (of success) for a unit change in x_k given that all of the other predictor variables remain constant. We note that this is completely analogous to the interpretation of the regression coefficients in multiple linear regression. Thus, holding the remaining predictors at some fixed set of values and not allowing them to vary with any changes in x_k, a single unit increase in x_k, is predicted to increase or decrease the log odds of success by an amount β_k. Equivalently, a single unit increase in x_k increases or decreases the odds of success *multiplicatively* by a factor of $\exp(\beta_k)$. Finally, we remark that the multiple logistic regression model given by eqn [6] can also be expressed equivalently in terms of π,

$$\pi = \frac{\exp\left(\beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_p x_p\right)}{1+\exp\left(\beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_p x_p\right)} \qquad [7]$$

In Section Interpretation of Logistic Regression Coefficients, we remarked that one of the appealing properties of logistic regression is that the same odds ratio can be estimated from either a prospective or retrospective study design. This result readily generalizes when x is quantitative rather than dichotomous, and also when there are two or more predictor variables. Thus, in a retrospective study $\beta_1, \ldots, \beta_p$ can be estimated by analyzing the data as if they had been obtained from a prospective study. That is, the data from a retrospective study can be treated as prospective data in a logistic regression analysis where the binary outcome of interest is modeled as the response variable. A formal proof of this result can be found in Farewell (1979) and Prentice and Pyke (1979). The only parameter that cannot be estimated with data from a retrospective study is the intercept, β_0, since it is determined by the proportions of 'successes' ($Y=1$) and 'failures' ($Y=0$) selected into the study. In many studies, however, the intercept is not of direct scientific interest.

Estimation

In this section we very briefly discuss estimation of the logistic regression coefficients. This section is somewhat more technical in nature than the previous sections and can been skipped over on a first reading of this article. Recall that in linear regression we estimate the linear regression coefficients using the method of least squares. That is, the least squares criterion chooses values for the linear regression coefficients that minimize the sum of squared deviations of the observed Y from the predicted values of Y, say $\widehat{Y}$, under the assumed regression model. The least squares method yields estimates of the regression coefficients that are also the *maximum likelihood* estimates when the errors have a normal distribution with constant variance. We use the more general method of maximum likelihood estimation for logistic regression.

The essential idea behind maximum likelihood is quite simple, and in fact is conveyed by its name. The method chooses values of the logistic regression coefficients that are most likely (or most probable) to have generated the observed data. This is achieved by maximizing the *likelihood function* for the data. The likelihood function is simply the probability of the response variables evaluated at the observed values, regarded as a function of the unknown logistic regression coefficients. Construction of the likelihood function requires that we must make an assumption about the probability distribution of Y. Fortunately, with a binary response, the selection of a probability distribution is straightforward as there is only a single distribution to choose from, namely the Bernoulli distribution.

In the following we assume that there are independent observations of the response variables Y_i and the predictor variables $x_{i1}, x_{i2}, \ldots, x_{ip}$ available on N individuals. The N binary responses, Y_i ($i=1, \ldots, N$), can be regarded as independent Bernoulli random variables, with $\pi_i = E(Y_i) = \Pr(Y_i=1)$. Since the N binary responses are independent the joint probability of ($Y_1, \ldots, Y_N$) is the product of the N Bernoulli functions. Thus, the likelihood function can be expressed as the product,

$$\prod_{i=1}^{N} \pi_i^{y_i}(1-\pi_i)^{1-y_i}$$

It is this function, or equivalently, the logarithm of the likelihood function, that must be maximized. Note that the likelihood is a function of the unknown logistic regression coefficients, since

$$\pi_i = \frac{\exp(\beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \cdots + \beta_p x_{ip})}{1 + \exp(\beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \cdots + \beta_p x_{ip})}$$

The maximum likelihood estimates of the logistic regression coefficients are obtained by substituting the above expression for π_i into the likelihood function and finding the value of the logistic regression coefficients that produce the largest value for the likelihood function. Ordinarily, the likelihood function has only a single maximum. Maximization of the likelihood, or the log likelihood, requires an iterative procedure and this has been implemented in many of the commercially available statistical software packages (e.g., SAS, STATA, and SPSS). A description of the iterative procedure can be found in, for example, McCullagh and Nelder (1989: pp. 40–43). Finally, estimates of the standard errors of the estimated logistic regression coefficients can readily be obtained using the method of maximum likelihood estimation.

Example

Next we consider an application of logistic regression to illustrate how the model can be used in practice. **Table 1**, adapted from Clogg (1982), contains data from 1518 individuals who participated in the US General Social Survey (Davis, 1977). The data are composed of a pair of 2×4 cross-classifications on the relationship between reported happiness (not too happy versus pretty or very happy) and completed years of schooling (less than 12, 12, 13–16, 17 or more), by the gender of the respondent. The goal of the analysis is to describe how reported happiness is related to years of schooling and the gender of the respondent. In particular, it is of interest to determine whether reported happiness is related to the amount of schooling received and whether this relationship is different for males and females.

We first consider a logistic regression model that includes effects of years of schooling, gender, and their interaction (model 1):

$$\log[\pi/(1-\pi)] = \beta_0 + \beta_1 G + \beta_2 \mathrm{YSC}_1 + \beta_3 \mathrm{YSC}_2 + \beta_4 \mathrm{YSC}_3 + \beta_5 G \times \mathrm{YSC}_1 + \beta_6 G \times \mathrm{YSC}_2 + \beta_7 G \times \mathrm{YSC}_3$$

Table 1 Cross-classification of U.S. sample according to reported happiness and years of schooling, by gender

		Years of school completed			
Gender	Reported happiness	<12	12	13–16	≥17
Males	Not too happy	40	21	14	3
	Pretty or very happy	213	177	167	54
Females	Not too happy	62	26	12	3
	Pretty or very happy	242	283	171	30

where $G = 1$ if female and $G = 0$ if male, and YSC_1, YSC_2, and YSC_3 are three *indicator variables* for the 4 levels of years of schooling. That is, $\mathrm{YSC}_1 = 1$ if years of schooling <12 and $\mathrm{YSC}_1 = 0$ otherwise; $\mathrm{YSC}_2 = 1$ if years of schooling is 12 and $\mathrm{YSC}_2 = 0$ otherwise; $\mathrm{YSC}_3 = 1$ if years of schooling is 13–16 and $\mathrm{YSC}_3 = 0$ otherwise. Maximum likelihood estimates of the regression coefficients for model 1 are given at the top of **Table 2**.

Note that since all of the predictor variables are discrete, this is a *saturated model* and will perfectly fit or predict the data in **Table 1**. Examination of **Table 2** reveals that the three estimated coefficients for the interaction of gender and years of schooling are relatively small when compared with their respective standard errors. A formal test of the interaction can be constructed by fitting a logistic regression model that omits the interaction and comparing the likelihoods for the two models (e.g., *see* Hypothesis Testing in Statistics). Next, we consider a logistic regression model that includes only the effects of years of schooling and gender (model 2):

$$\log[\pi/(1-\pi)] = \beta_0 + \beta_1 G + \beta_2 \mathrm{YSC}_1 + \beta_3 \mathrm{YSC}_2 + \beta_4 \mathrm{YSC}_3$$

Maximum likelihood estimates of the logistic regression coefficients in model 2 are given in the middle of **Table 2**. Comparing model 2 to model 1 in terms of their likelihoods, we can formally test the null hypothesis of no interaction, $H_0{:}\beta_5 = \beta_6 = \beta_7 = 0$. The likelihood-ratio chi-squared statistic is 2.99 on 3 degrees of freedom ($p \approx 0.4$). Thus, we cannot reject $H_0{:}\beta_5 = \beta_6 = \beta_7 = 0$, and model 2, without an interaction between gender and years of schooling, is defensible. This implies that the relationship between reported happiness and years of schooling is the same for males and females. Examination of the estimated regression coefficients for years of schooling in model 2 suggest that a further simplification of the model might be possible. The effect of years of schooling on reported happiness appears to be greatest for those individuals with less than 12 years versus those having 12 or more years of education. Thus, we next consider the following logistic regression model (model 3):

$$\log[\pi/(1-\pi)] = \beta_0 + \beta_1 G + \beta_2 \mathrm{YSC}_1$$

Note that in this model we have combined the levels of years of schooling completed to form a dichotomy: less than 12 years versus 12 or more years. Maximum likelihood estimates of the regression coefficients in model 3 are given at the bottom of **Table 2**. Comparing model 3 to model 2 in terms of their likelihoods provides a formal test of the null hypothesis, $H_0{:}\beta_3 = \beta_4 = 0$. The likelihood-ratio chi-squared statistic is 1.46 on 2 degrees of freedom ($p \approx 0.5$) and thus the null hypothesis cannot be rejected. The estimated logistic regression coefficients for model 3 indicate that the overall reported rates of happiness are very similar for males and females but that the rates of reported happiness are substantially lower for those with less than 12 years of education. In particular, the odds of reported happiness for those with 12 or more years of schooling is 2.5 (or $\exp[0.9178] = 2.50$) times greater (with 95% likelihood-based confidence interval: 1.83, 3.44) than for those with less than 12 years of schooling. That is, the ratio of odds of reported happiness is 2.5 when those with more than 12 years of schooling are compared to those with less than 12 years of schooling. Finally, the nature of this

Extensions of Logistic Regression

In this section we briefly review a number of more advanced topics that can be considered extensions of the standard logistic regression model: conditional logistic regression, exact logistic regression, and logistic regression for clustered data.

Conditional Logistic Regression

The previous sections showed that logistic regression is a very versatile model for assessing the associations between a binary response and a set of predictors. This section introduces a related technique known as *conditional logistic regression*, which extends many of the benefits of logistic regression to studies with *matched* designs. In matched study designs, individuals are stratified on the basis of variables thought to be related to the outcome variable of interest. For example, age and socioeconomic status are two variables commonly used to define strata in many studies in the social and behavioral sciences. The conditional logistic regression model used to analyze matched data is

$$\log\left[\pi_j/(1-\pi_j)\right] = \alpha_{j0} + \beta_1 x_{j1} + \beta_2 x_{j2} + \cdots + \beta_p x_{jp} \qquad [8]$$

Note that this is similar to the standard logistic regression model given by eqn [6], except that the probability of success and the predictors are now indexed by j to indicate that they apply to individuals (or units) from the jth stratum (e.g., matched pair), $j = 1, \ldots, S$. There can be any number of individuals in the jth stratum; however, for estimation (discussed later) there must be at least one success ($Y = 1$) and one failure ($Y = 0$) in each stratum. Note also that the common intercept β_0 in standard logistic regression has been replaced in eqn [8] by S stratum-specific intercepts denoted by α_{j0} ($j = 1, \ldots, S$), but the remaining regression coefficients are assumed constant over the strata.

Although the conditional logistic regression model bears much similarity to the standard (or unconditional) logistic regression model, there are some subtle but important differences. First, the stratum-specific intercepts, α_{j0}, are considered nuisance parameters and cannot be estimated when there are few observations in each of the strata. This is usually not of any concern since, as for standard logistic regression, these intercepts are generally not of scientific interest. Second, because the model includes stratum-specific intercepts, the β's now have stratum-specific interpretations in terms of changes in the log odds of success for within-stratum changes in the predictors. That is, the β's have interpretation assuming the level of the matching factors is held constant. For example, β_k has interpretation in terms of changes in the log odds of success for a single unit change in x_{jk} *within the* jth *stratum* (i.e., comparing two individuals within the same stratum that happen to differ by one unit in the kth predictor). Third, the associations between any variables used for matching (or any other covariates that are constant within strata) and the outcome cannot be quantified. This is because the method of estimation is based entirely on variation within a stratum; conditional logistic regression cannot be used to estimate the effect of a covariate that varies only between strata (but not within a stratum).

Next we consider estimation of the conditional logistic regression model parameters. One naive approach to fitting this model would be to attempt to estimate all of the parameters, including the stratum-specific intercepts. However, for matched designs, the number of strata grows as the sample size increases, which means that the number of parameters would be large relative to the sample size no matter how large a sample was collected. For example, in a matched-pair design with N pairs (i.e., two subjects in each stratum), such an analysis would require the estimation of $N + p$ parameters from a sample of only $2N$ observations. It should not be too surprising that this proliferation of stratum-specific intercepts

causes problems for estimation; when the number of these nuisance parameters is comparable to the number of observations, the maximum likelihood estimates of the β's may be far from their true values. In general, the standard properties of maximum likelihood break down when there are few observations in each strata. To circumvent this, a variant of the approach, *conditional maximum likelihood*, can be used in these settings. Conditional logistic regression maximizes a likelihood for the conditional distribution (and hence the term 'conditional' logistic regression) that eliminates these stratum-specific intercepts and bases estimation of the associations between the predictors and response entirely on information from within the strata. As such, conditional logistic regression allows for estimation of the β's, the parameters of real scientific interest, at the expense of ignoring those parameters of far less interest. In order to estimate the β's it is necessary to have at least one success and one failure in each stratum. The term conditional means we condition our results on the successes and failures recorded in each stratum. This enables the use of logistic regression with matched designs.

Exact Logistic Regression

Recall that in simple logistic regression with a single dichotomous predictor, x, a test for no association ($\beta_1 = 0$) can be constructed based on the *Wald test* statistic, given by:

$$Z = \frac{\widehat{\beta}_1}{\sqrt{\widehat{\mathrm{Var}}\left(\widehat{\beta}_1\right)}} = \frac{\widehat{\beta}_1}{\widehat{\mathrm{SE}}\left(\widehat{\beta}_1\right)}$$

which, in large samples, has an approximate standard normal distribution under the null hypothesis of no association; equivalently, the squared Wald test statistic, Z^2, has an approximate chi-square distribution with 1 degree of freedom. Alternatively, the *likelihood-ratio test* statistic can be used and this is simply twice the difference in the log-likelihood under the alternative ($\beta_1 \neq 0$) and null ($\beta_1 = 0$) hypotheses. In large samples, the likelihood-ratio chi-square statistic has an approximate chi-square distribution with 1 degree of freedom. For logistic regression, the Wald test is known to exhibit unreliable and aberrant behavior that leads to very low power in certain practical circumstances; as a result, the likelihood-ratio test is preferred. Although most statistical software packages routinely report Wald tests, many provide options for producing likelihood-ratio tests (and likelihood-based confidence intervals).

If the sample size, N, is relatively small, these asymptotic or large sample approximations cannot be relied upon. In particular, a rule of thumb in statistical folklore is that the asymptotic approximations cannot be relied upon if one (or say 25%) of the cells in the 2×2 table of the cross-classification of Y and x has an estimated expected count less than 5. When at least one of the estimated expected counts is less than 5, and it is of interest to make inferences about the association, a common technique is to fix both margins of the 2×2 table and use so-called 'exact' tests and confidence intervals. That is, for a prospective study (where the row margins in Figure 2 are fixed), we further condition on the column margins; for a retrospective study (where the column margins are fixed), we further condition on the row margins; or for a cross-sectional design (where only N is fixed), we condition on both row and column margins. In all of these cases it can be shown that the counts in the resulting table with fixed margins have a noncentral hypergeometric distribution. Under the null hypothesis H_0: $\beta_1 = 0$, the noncentral hypergeometric becomes a central hypergeometric distribution, which forms the basis of Fisher's exact test of no association in a 2×2 contingency table (see, for example, Fisher, 1934). This test is appropriate in small samples; the noncentral hypergeometric can also be used to obtain an estimate of the odds ratio that has better small sample properties than the usual odds ratio estimate given by $e^{\widehat{\beta}_1}$ in eqn [2]. A potential drawback with Fisher's exact test, however, is that it can be 'conservative' in the sense that the true significance level is often far smaller than the nominal level (e.g., 0.05), thereby making it more difficult to reject the null hypothesis.

In general, multiple logistic regression analysis with many predictors relies on large sample theory for the validity of its results. In particular, maximum likelihood estimation of the logistic regression parameters can perform poorly when the sample size is small, the probability of success is near one or zero, or when there is an insufficient number of successes or failures for certain combinations of the predictor variables. *Exact logistic regression* (see, for example, Mehta and Patel, 1995) is an alternative method for fitting logistic regression models that produces valid estimates, test statistics, and confidence intervals when data are sparse. The relationship of exact logistic regression to maximum likelihood logistic regression is similar in certain ways to the relationship of Fisher's exact test to large-sample methods for 2×2 contingency tables. However, whereas Fisher's exact test conditions on the row and column totals in order to derive the distribution of the test statistic, exact logistic regression conditions on the so-called *sufficient statistics* for the remaining parameters in the model when estimating each logistic regression parameter. The sufficient statistics for the parameters are determined by the number of successes for different values of the corresponding predictors. Similar to Fisher's exact test and other exact methods, exact logistic regression guarantees that tests conducted at the α significance level have a type I error rate less than or equal to α, and that 95% confidence intervals have at least 95% coverage even for small sample sizes and sparse data. Parameter estimates and confidence intervals have interpretations identical to those for maximum likelihood logistic regression.

Although the theory underlying exact logistic regression has been well established since the 1970s, the computations required of the method were so demanding that its implementation was considered impractical. More recently, however, with the development of efficient algorithms coupled with increasingly fast computers, exact logistic regression routines are implemented in many statistical software packages.

In summary, exact logistic regression overcomes problems due to sparse data. In principle, exact logistic regression can be applied in settings with multiple predictors; however, greater care is required when attempting to fit complex models. The method has some potential disadvantages. In particular, it may be overly conservative in settings when maximum likelihood logistic regression performs adequately. In addition, it can be

computationally intensive, especially when quantitative predictors or a large number of categorical predictors are included in the logistic regression model. When feasible, exact logistic regression is an attractive alternative to maximum likelihood logistic regression in small sample and sparse data settings.

Logistic Regression for Clustered Data

So far, we have considered logistic regression for a single binary response or in settings where all responses are independent. However, multivariate binary response data commonly arise in a number of applications in the social and behavioral sciences. That is, two or more measurements of the response are often obtained in a block or *cluster* and the binary responses within a cluster are expected to be positively correlated. When this occurs the responses from any pair of members of the same cluster are expected to be more closely related than the responses from a pair belonging to different clusters. Some common examples where data arise in clusters include repeated measures or longitudinal studies and studies on families, communities, or other naturally occurring groups. The important aspect of all of these studies is that the binary responses within a cluster cannot be regarded as independent of one another.

There may be many reasons for the correlation among cluster members. For example, when the cluster is composed of all the siblings within a family the correlation among siblings may be due to shared (or at least similar) genetic, environmental, and social conditions. In a longitudinal study, where the responses within a cluster represent measurements taken at different occasions, the binary responses are expected to be positively correlated simply because they have been obtained on the same individual (or cluster). Whatever the underlying reasons for the correlation, failure to account for it in the analysis can lead to invalid inferences. That is, the standard application of logistic regression in this setting is no longer appropriate.

There are two general approaches for handling the analysis of clustered binary data. The first is to consider models for the joint distribution of the cluster of binary responses that explicitly account for the within-cluster correlation. There is an extensive statistical literature on this topic and the interested reader in referred to a review article by Pendergast et al. (1996). For the most part, these models can be computationally demanding and few have been implemented in commercially available statistical software. An alternative approach is to simply ignore the correlation among members of a cluster. That is, the analysis proceeds naively as though the binary responses within a cluster can be regarded as independent observations, but later a correction is applied to ensure that valid standard errors are obtained. Note that in this 'naive' approach that ignores the within-cluster correlation the estimated logistic regression coefficients are valid, but their nominal standard errors are not. However, valid standard errors can be readily obtained using the well-known empirical variance estimator, first proposed by Huber (1967). Thus, the analysis proceeds in two stages. In the first stage, the correlation among binary responses within a cluster is simply ignored and standard logistic regression is used to obtain estimates of the logistic regression coefficients. In the second stage, valid standard errors for the estimated logistic regression coefficients are obtained using an alternative, but widely implemented, variance estimator that properly accounts for the correlation among the binary responses. The chief advantage of this approach is that it can be readily implemented using standard statistical software for logistic regression (see, for example, Hosmer et al., 2013: Chapter 9).

Conclusion

In this article we have considered regression models for a binary response. In most fields, logistic regression has become the standard model for relating a binary response to a set of covariates. We have described the salient features of logistic regression and considered various aspects of interpretation of logistic regression coefficients. We remarked that the many appealing properties of the odds ratio probably account for the widespread adoption of the logistic function, and hence logistic regression, over alternative functions such as the log, probit, or complementary log–log functions. A more detailed discussion of some of the issues presented here can be found in the textbooks by Agresti (1996), Kleinbaum (1993), and Hosmer et al. (2013).

We conclude this article by noting that logistic regression happens to be a special case of a broad and unified class of statistical models known as *generalized linear models*. Other familiar examples of generalized linear models include linear regression and analysis of variance (ANOVA) models for a continuous response, log-linear models for count data, and probit regression for a binary response. It is beyond the scope of this article to give a detailed description of generalized linear models; the interested reader is referred to the textbooks by Dobson (1990) and McCullagh and Nelder (1989). Instead, we will simply outline the main features of generalized linear models and indicate how logistic regression is related to alternative models for binary responses.

Generalized linear models are characterized by a three-part specification: (1) the *random component*, where the distribution of the response variable is assumed to be from the exponential family (the exponential family includes, among others, the normal, Bernoulli and Poisson distributions); (2) the *systematic component*, where a set of predictor variables, say $x_1, \ldots, x_p$, produce a *linear predictor*, $\beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_p x_p$; and (3) the *link function* relating the random and systematic components. The link function in (3) describes how a particular transformation of the mean of the response variable is related *linearly* to the predictor variables. In summary, a generalized linear model describes how the transformed mean of a response variable from the exponential family of distributions is linearly related to a set of predictors. Thus, within the framework of generalized linear models, logistic and probit (or complementary log–log) regression share the same specification of the random and systematic components. What distinguishes logistic regression from probit regression is solely the choice of link function in (3). In logistic regression a logit function is chosen to link the random and systematic components, i.e., a logit function relates the probability of success, π, to the linear predictor. In probit regression the inverse normal function is chosen to relate π to the linear predictor.

Finally, we remark that the logit function also happens to be the so-called *natural* or *canonical* link function, i.e., the logit is a special link function that can be derived from the Bernoulli distribution. Although the choice of canonical link function does result in some minor mathematical simplifications, the selection of a suitable link function should primarily be made on scientific grounds. That is, the choice of link function should be based on the goodness of fit of the resulting model and the ease of interpretation of the model parameters. In the case of a binary response, we have already seen that for most practical purposes it is not possible to discriminate empirically, in terms of goodness of fit, between probit and logistic regression. As a result, logistic regression is often the method of choice for analyzing a binary response due to the more appealing interpretation and properties of the logistic regression coefficients.

Abstract

Alfred Binet's impact on the field of psychology is unequaled, with the possible exception of Sigmund Freud. In retrospect, it appears that quite ironically Alfred Binet's most outstanding contribution is the Stanford–Binet Intelligence Scale, which owes its popularity (though not its conceptualization) largely to the work of Lewis Terman rather than to Binet himself. The intelligence scale became the tree that hid the forest: Much of Binet's exceptional, and often revolutionary, research was largely ignored on account of the overwhelming visibility that his work on intelligence testing achieved. A thorough review of his bibliography shows that his research interests spread a wide range of topics, including but not limited to anatomy, animal magnetism, audition, chess players, court witnesses, double consciousness, fetishism in love, graphology, intellectual exhaustion, intelligence, intelligence assessment, hallucinations, hysteria, inhibition, language, literary creation, memory, mental alienation, mental images, moral responsibility, movement, pedagogy, perception, phrenology, physiology, reasoning, retardation and academic underachievement, the soul, and suggestibility. Though at first glance these topics may seem unrelated, there really are two consistent threads throughout Binet's life and work. The first is a commitment to experimental psychology. The second is his pursuit to understand the complexities of the human mind in order to establish 'an individual psychology.'

A Brief Biography

Alfred Binet was born in the seaport town of Nice on what was to become France's Mediterranean coast on 11 July 1857. According to later reports by his daughter Madeleine (Avanzini, 1974), Alfred was a bright child who succeeded so well in school that his mother decided to send him away to the capital Paris when he was barely 12 years old, in order that he might study in one of the best schools in France. Upon graduation from high school he completed a law degree (1877), but then decided to pursue studies in medicine and biology rather than practice law. Under the supervision of the entomologist and embryologist Balbiani, who was later to become his father in law, he started writing a dissertation on "The sub-intestinal nervous system of insects." At the same time he wrote plays for the theater, already displaying his characteristic eclectic range of interests. He finally found a discipline that allowed him to combine his different areas of interests: Psychology. To simplify, one can distinguish three phases in his career as a psychologist, although his publication record shows that the stages were overlapping rather than sequential (Delay, 1958): Psychopathology, experimental psychology, and child psychology.

In the second half of the nineteenth century, French psychology was mainly focused on psychopathology, and Binet's early interests were no exception. His early influences were the memory researcher Théodule-Armand Ribot and neurologist Jean-Martin Charcot, and Binet's first major writings explored the domains of sensations, hysteria, hypnotism, and personality disorder. Binet worked closely with Ribot between 1880 and 1907, and published over 40 articles in Ribot's *Revue Philosophique*. During this period, he also began studying hypnotism under Charcot at the Salpetrière hospital in Paris.

In 1891, Binet received tenure at the physiological psychology laboratory at the Sorbonne University in Paris, and his research focus shifted from clinical to experimental psychology. The major contemporary influences in psychophysiology and experimental psychology were German, namely Wilhelm Wundt whose laboratory in Leipzig served as the model for the one Binet founded in Paris. Binet completed his thesis in biology in 1895, the same year in which he took the head of the physiological psychology laboratory where he had tenure, and published a seminal *Introduction to Experimental Psychology*. 1895 was also the year in which he founded the journal *L'Année Psychologique*, still published and considered a reference today. In 1899, Binet took on Theodore Simon, who was to become his closest and most constant collaborator, as a doctoral student and that same year he joined the *Free Society for Psychological Child Studies*, of which he became the president in 1902. Like many researchers of his time, Binet decided to follow in the footsteps of neurologist Paul Broca, and explored intelligence through phrenology, exploring the direct relation between the size of the cranium and a person's level of intelligence. Binet's empirical investigations consisted in measuring the crania of school children deemed bright by their teachers and to compare these with the measurements obtained from academically low-achieving students. In 1901, Binet conceded that "the idea of measuring intelligence by measuring the head … seemed ridiculous" (Binet, 1901: p. 403). Later, however, he did discover that there were noticeable differences in the cranial size and shape of children from contrasted groups, with very bright students having larger skulls than very low-achieving students. Binet himself reached the conclusion that the initial measures showing cranium size differences between low- and high-achieving students were probably due to his own suggestibility. With a rare sense of honesty, he admitted that he had been looking for differences and had found them where he had expected them, and with his faith in phrenology shaken, he abandoned it. He similarly discarded hypnosis as a method of study, and moved instead to explore the human psyche through tests and puzzles that he initially

created for, and validated on, his two daughters (Binet, 1890). As was the case with Jean Piaget many years later, most of his hypotheses regarding cognitive development stemmed from the observation of his own children.

After a phase devoted the psychopathology, followed by one centered on experimental psychology, the third phase of Binet's life focused primarily on child psychology. The start of this period can be traced to 1905, with the publication of several articles by Binet and Simon devoted to the diagnosis of abnormality (Binet and Simon, 1905a,b,c) and the establishment of a laboratory in experimental psychology. In the laboratory Binet worked closely with classroom teachers, and it is here that he made his major contributions to the study of academic underachievement, but also to psychometrics, a term coined by Sir Francis Galton in 1879. Another of Binet's major contributions to child psychology was promoting the idea that children are not, as previously thought, miniature adults, but follow different principles of cognitive functioning (Zazzo, 1958). The rest of this article will focus on Alfred Binet's contributions to our understanding of abnormal children and the development of the assessment tools to which this interest led.

Alfred Binet passed away unexpectedly on 28 October 1911, at age 54, and was laid to rest in the Montparnasse cemetery in Paris, France.

The Study of Abnormal Children

Starting with the beginning of the nineteenth century, Binet increasingly focused his research on the study of 'abnormal' children (Binet and Simon, 1907). The *Free Society for Psychological Child Studies*, presided by Binet, lobbied the French government to start assessing school children, with the aim of early identification of those children that would not benefit from regular schooling in order to provide them with special education. Though this is an established practice in many countries today, at the time it was quite novel and controversial. In 1904, the French minister of education officially appointed Binet to devise a means of identifying 'retarded' school children (see also Sternberg and Jarvin, 2003) and out of these efforts came the publication in 1905 of Binet and Simon's Metric Intelligence Scale (Avanzini, 1974). The scale identifies students with learning impairments who were nevertheless thought able to profit from education and to allow them into special education classes. The first 'perfectioning class' was opened in 1907, and two more such specialized classes followed that same year. Though Binet admitted starting out with the belief that all children could progress and 'abnormality' to a certain extent be overcome, he never lost sight of the importance of empirically testing and validating his ideas. In that spirit, he asked that the usefulness of special education classes be empirically established before any legislative measures to generalize their use be taken.

Through his experience with developing assessments for selecting students into special education classes and working with teachers on adapted pedagogical methods, Binet strengthened his belief in psychometric assessment and further refined his theoretical ideas about 'abnormality.'

Binet and Simon's (1907) publication *Abnormal Children* proposed a new view of mental retardation in which an abnormal child is not a normal child who has either halted or slowed down in its development, but rather a child who follows a different developmental pattern. This pattern is unbalanced and uneven, with some aspects resembling the developmental patterns of 'normal' children and others being quite different. It is precisely this lack of balance between the different developmental aspects that constitutes the abnormality (Binet and Simon, 1907, 1922). In the 'abnormal' child, there might be an important delay in the acquisition of certain aptitudes, while other aspects, be they cognitive or somatic, follow a normal pattern of development.

Binet and Simon were also precursors in arguing that the age at which one acquires a skill has specific impacts and implications. For example, learning to read at age six is different from learning to read at age 12. The abnormal child who learns to read at age 12 has a more extensive vocabulary and more extrascholastic interests than the regular 6-year old when he or she learns to read. Intellectual impairment can be characterized by three major components: a global developmental delay, the imbalance of this delay depending on what cognitive functions are considered, and the resulting lack of coordination in cognitive functioning. Because abnormality is a distinctive developmental pattern rather than mere retardation in a normal developmental pattern, special education is possible and needed.

The Metric Intelligence Scale

Binet and Simon's Intelligence Scale published in 1905 contained 30 tests, presented in order of increasing difficulty, and designed to measure everything from basic skills such as coordination of movement to more complex processes such as comprehension, judgment, and abstract reasoning. Some of the tests were specifically created for the Scale and some were adaptations of existing cognitive assessments, like those created by French physicists Blin and Damaye. The entire battery of tests was piloted on samples of 'normal' and 'retarded' children from ages 2 to 12.

Performance on the easiest tests distinguished severely and profoundly retarded children (then labeled 'idiots') from the rest; tests of intermediate difficulty distinguished between the severely and the moderately retarded (then labeled 'imbeciles'); and the most complex tests lead to different performances for mildly retarded (then labeled 'morons') and normally functioning children of the same age. The tests also distinguished between younger and older children.

As a member of the ministerial committee on education, Binet's main purpose was to identify those mildly retarded children thought most likely to benefit from special education in order to enhance their cognitive functioning. The 1905 version of the Intelligence Scale stressed that the results of the tests only be used as an indication of a child's cognitive level at the time of administration, and that this level was likely to change with appropriate and adapted education. A revised version of the Scale, published in 1908, offered the possibility to establish a child's mental age (a notion first introduced by Chaillé in 1887) based on his or her performance. If 65–75%

of children in a given age group respond correctly to a given test, that test is considered to be appropriate to measure mental performance for that age group. A child can thus succeed on tests that are classified as being lower, equal to, or higher than that child's biological age. It should be noted that the mental age thus derived simply corresponds to the performance norm of a given age group, and does not indicate the developmental stage reached by the child, contrary to what the American adapters of the Scale later thought. In other words, having a given mental age does not imply that you function like a child of that biological age, but only that your individual performance on a given test corresponds to what the majority of children at a given age will achieve.

Binet explicitly warned against the use of performance on an IQ test as a fixed measure of intelligence: by essence, the test is constructed in such a manner that 25–35% of children of a given age group will fail on a test intended for their age (Lippman, 1922).

Binet also made it clear that the results on the Scale were just one among several indicators of the child's level of functioning, and that the careful observation of the global person and the test taker's reactions to the assessment situation were as important to take into consideration as the numerical tests results per se. As a researcher, Binet was less interested in the end results than in the paths by which they were reached by different children.

To paraphrase an article by Sarason (1976), the fate of Alfred Binet and school psychology was unfortunate, and the misinterpretations and misuses of the Metric Intelligence Scale were many. Binet's aim was to develop and validate an instrument that would help identify those children, who would benefit from special education and allow them to make the most of their potential in adapted pedagogical settings. His aim was to prevent further rejection of these children by providing them the special education that would allow them to thrive and eventually to return to the regular classroom. This second aspect, however, is all too often neglected, and the Scale used to weed out students rather than a means to strive for greater inclusion.

It is important to remember that Binet did not view intelligence as a fixed quantity set at birth, but rather as incremental. It is precisely because of the elastic nature of intelligence and the possibility of developing it through education that we must identify children with special needs to provide them the support that will allow them to develop their intellectual abilities and to blossom. The researchers who imported the Intelligence Scale to the United States and Great Britain, however, had different views and different goals in mind. Lewis Terman, who in 1916 introduced the Scale as the Stanford–Binet assessment instrument in the United States, stressed the importance of hereditary factors in explaining performance on intelligence tests. If intelligence is largely hereditary, specialized education becomes less important, and in that his use of the Scale goes against that originally intended by Binet. Terman considered the genetic influence to be too strong to be altered through education. For Terman, children with low scores on the tests should be put in separate classes, not because they would there receive the specialized and adapted education that would allow them to thrive and then return to the regular classroom, but because there was no possibility of them ever being able to integrate into a regular classroom and benefit from regular instruction. Low-achieving students should thus be set aside and the State would have to assume guardianship of those with intelligence levels in the mentally retarded range (Terman, 1916).

Strengths and Weaknesses of Binet's Contributions to Social and Behavioral Sciences

Binet's strengths and weaknesses are very much the two sides of the same coin: His strength is the applied nature of his research and the lasting social cultural impact of his work, his weakness the lack of a global, coherent theoretical framework. Key to his research is the pragmatic approach and attempt to directly connect empirical research results to social and educational concerns. His research on abnormal children and cognitive assessment started not as a theory, but in response to a concrete problem, that of educating more children than what were at the time benefiting from regular instruction.

That is not to say that his work had no theoretical basis, and he is perhaps best remembered for two major theoretical contributions. First, he broke with the Galtonian tradition of studying intelligence through psychophysical processing. He suggested instead that intelligence be studied through the expression of higher order processing in complex everyday tasks. Though this viewpoint may seem trite today it was novel at the time, and almost provocative to many of his contemporaries. Before Binet, most psychologists followed in Wundt's footsteps and thought that intelligence was best explored by measuring lower order, very simple, processes. Binet not only decided to assess higher order cognitive functions, he decided to do so with the same experimental rigor that had previously been reserved for lower order processes. Second, he introduced a new methodology for studying intelligence.

Though it is difficult to find a global theory of intelligence in Binet's work (Reuchlin, 1977), it is clear that he did think in theoretical terms. In his publications, intelligence is variously assimilated to common sense, faculty to adapt, initiative, judgment, and practical sense. At other times, intelligence is decomposed into four 'functions': comprehension (understanding), direction, invention, and self-censorship. Neither Binet's head nor his heart was in theorizing about intelligence, however, and he went so far as to state that he was only interested in understanding the specific facts that he gathered and not in any general theory of intelligence.

Psychological Assessment Today

The importance of psychometrically sound assessment scales to measure levels of cognitive functioning was soon generalized beyond the population of abnormal school-aged children and constitutes one of Binet's greatest legacies to the field of cognitive evaluation. The strong positive correlation between children's scores on the *Binet–Simon Metric Intelligence Scale* and their school performance, largely due to the very scholastic nature of any of the assessment battery's tests, was

seen as a proof that the scale was indeed measuring intelligence, and contributed to its widespread success. The Stanford–Binet is still used today, although its prominence has been eclipsed by the Wechsler scales.

The debates triggered by Binet's work are alive and well; however, intelligence and intelligence testing remaining hotly debated topics, as demonstrated by the steady crop of new books to appear on the subject every year.

Bioarchaeology

Abstract

Bioarchaeology is the study of human remains from archaeological contexts. The field focuses on a range of circumstances that shape who we are today, including health and well-being, diet and nutrition, environment and human impacts, and the influence of social, economic, and political forces on the lives and livelihoods of past societies in recent human evolution.

Bioarchaeology is the study of human remains from archaeological settings, viewing these remains in relation to biocultural adaptation, life history, lifeway reconstruction, population and demographic history, and the influence of social, economic, and political forces on the lives and livelihoods of earlier societies (Agarwal and Glencross, 2011; Buikstra and Beck, 2006; Larsen, 1997). Human remains can include any body tissue, ranging from artificially or naturally preserved bodies – such as mummies from Egypt or bog bodies from Denmark – to fragments of bones and teeth. Because skeletons are preserved far more often than other types of remains, they comprise most of the subject matter of bioarchaeology.

Origins and Paradigm Shifts: From Racial Classification to Biological Process

Bioarchaeology originated in the field of osteology, the anatomical study of bones and teeth. Much of the history of study of ancient skeletons focused on classification and racial typology. Biological differences between populations from different time periods – such as differences in skull form – were interpreted to represent replacement of one 'race' of people by another. Various lines of evidence reveal the adaptability of bone tissue, especially with regard to influence of physical activity on shape and structure. For example, skulls representing earlier populations who lived exclusively on wild plants and animals tend to be larger and more robust than skulls representing later farmers (e.g., Carlson and Van Gerven, 1977). In consideration of the extrinsic factors that influence skull form (e.g., shift from chewing hard- to soft-textured foods), the temporal variation for many settings is best interpreted in light of underlying biological processes that influence musculoskeletal development and not racial history.

The reinterpretation of temporal changes in skull form is emblematic of the paradigmatic shift that took place in bioarchaeology in the last 40 years (Larsen and Walker, 2010). Namely, ancient bones and teeth are no longer viewed as objects for classification only. Rather, bioarchaeologists seek to understand ancient skeletons as though the populations they represent are alive today, subject to the myriad of environmental, cultural, and social influences that affect human biology.

Skeletal and dental tissues are remarkably sensitive to a variety of environmental conditions affecting their form and composition. Owing to this sensitivity during life, human remains recovered from archaeological settings are informative about quality of life (health) and lifestyle (activity and work) in particular, and behavior in general. Skeletons also contain a fund of information about biological relatedness and demographic history.

Quality of Life and Health

Quality of life refers to a variety of factors that influence physical well-being – health is the most important. Health is assessed from human remains via chemical, stress, pathological, and morphological indicators.

Reconstructing Diet and Inferring Nutrition: Stable Isotopes and Bone Chemistry

The food humans eat and the nutrition that it provides is fundamental to health. Until the 1980s, most knowledge about ancient diets was based on plant and animal remains from archaeological contexts. In the late 1970s, Vogel and Van der Merwe (1977) identified the timing and intensity of the shift from diets based on wild plants to domesticated plants (maize) by analyzing stable isotope ratios of carbon ($^{12}C/^{13}C$) extracted from archaeological human bone samples. This pathbreaking study provided a new basis for reconstructing past diet and set the stage for analysis of stable isotopes of other elements (e.g., nitrogen, strontium, and oxygen) and drawing inferences about variation in diet, food use, weaning practices, climate, mobility, and social structure of past societies (Dupras and Tocheri, 2007; Katzenberg, 2008).

Stress and Deprivation

The cells responsible for tooth and bone development are easily disrupted if physiological stress caused by malnutrition or disease occurs while these tissues are forming. In teeth, macroscopically visible areas of enamel deficiency (hypoplasia) or microscopically visible defects (accentuated Retzius lines) indicate growth disruption. In addition to having elevated frequencies of indicators of growth arrest, populations that experience chronic illness or malnutrition tend to be short in stature and have less bone mass in comparison with healthy, well-nourished populations.

Many human populations experience nutritional deficiencies, infection and infectious disease, or poor living

circumstances generally (e.g., Walker et al., 2009). Anemia often develops, resulting in increased production of a person's red blood cells. The skull bones of anemic persons are often thickened and display porosity (porotic hyperostosis). The incidence of growth arrest indicators, anemia, and other related morbid conditions increased in the last 10 000 years as human populations shifted to agriculture and became sedentary.

Illness and Infection

Throughout the entire 5 million or so years of human evolution, human beings have been exposed to many different microbes, many of which cause disease. Skeletons record the effects of a number of chronic diseases, such as the treponematoses (the disease group that includes the nonvenereal and venereal forms of syphilis), leprosy, and tuberculosis. Identification of deoxyribonucleic acid (DNA) in archaeological skeletons has verified that the lesions found in ancient remains result from the disease-causing microbes (e.g., *Mycobacterium tuberculosis*; Klaus et al., 2010; Salo et al., 1994).

Leg (tibia) and, to a lesser extent, other bones in archaeological skeletal samples sometimes display periosteal reactions, areas of pathological bone apposition. These lesions are nonspecific because they can be caused by different infectious agents or by trauma to the lower leg. For many settings, these lesions are likely due to population crowding and poor hygiene, conditions conducive to the maintenance and spread of infectious disease. Sedentary, crowded populations in prehistory have generally higher frequencies of nonspecific and specific infectious disease than mobile, dispersed populations.

Violence and Injury

All human populations experience physical confrontation of one type or another at some point in time. In the Santa Barbara Channel Island region of the southern California Pacific coast, numerous skulls display indentations (depressed fractures) caused by being struck on the head with a club (Lambert and Walker, 1991). In late prehistory in this setting, the frequency of cranial fractures increased, and lethal projectile wounds became more common than before. This temporal shift coincides with deterioration in climate and reduced availability of food resources, suggesting that as environmental stress increased, people became more competitive and more violent. The skeletal evidence derived from the victims of violence may be more informative about the causes and consequences of confrontation than other archaeological evidence (e.g., fortifications, iconography, and weaponry) (see Tung, 2012).

Lifestyle and Activity

Physical activity is a defining characteristic of different human adaptive regimes. Hunter-gatherers are often characterized as highly mobile, living demanding lifestyles that require a great deal of work in order to acquire food. Agriculturalists, on the other hand, are often thought of as being more 'advanced,' leading lives of leisure. Study of ancient skeletons allows us to address these assumptions and to test hypotheses about labor, workload, and physical activity in past societies.

Activity and Degenerative Pathology

The articular surfaces of the joints of the skeleton are adapted to withstand mechanical stress, such as those that derive from lifting or walking, or a combination of activities. Over the course of a person's lifetime, the cartilage and bone in the articular joints (e.g., knees) begins to erode in response to mechanical loading. In addition, spicules of bone form along the joint margins, which may impede movement. These bone changes are part of a disorder called osteoarthritis. In archaeological settings, there is a tendency for skeletons of prehistoric hunter-gatherers to have more osteoarthritis than those of prehistoric farmers, and males generally have more osteoarthritis than females (see Bridges, 1992; Larsen, 1995). However, the pattern and frequency of osteoarthritis is highly variable from one region to another, suggesting that the disorder is influenced by local circumstances involving a complex interplay between culture and lifestyle.

Activity and Bone Structure

Bone tissue remodels itself in response to mechanical stimulation (Wolff, 1892/1986). In areas of the skeleton (or a particular bone) that are subjected to high levels of physical demand, more bone tissue is added in order to add strength and to resist forces that would cause fracture. Breadths and circumferences (e.g., for leg and arm bones) can be used to characterize the size of bones, and to infer levels and types of physical activity. Engineers have developed a more precise way of inferring levels or types of physical activity. Civil and mechanical engineers measure the strength of beams that are used in the construction of buildings. The distribution of material in cross sections of these beams is analyzed in relation to how they are able to resist bending, twisting (torsion), and other loading modes. Similarly, the human skeleton provides the body with a superstructure for the support of body weight and the action of muscles. From cross-sectional measurements of bones (derived from computed tomographic scans or by direct cutting to reveal the cross sections), bioarchaeologists apply these engineering principles and methods to determine the strength of bones (Ruff, 2008). Biomechanical analysis of skeletons from around the world shows a general reduction in bone strength over the course of human evolution, especially in the last 10 000 years, suggesting that physical activity has declined.

Activity above the Neck

The size and morphology of the face and jaws is influenced by mechanical loading and activities involving mastication of food, and in the use of teeth in nondietary roles (e.g., use of front teeth for preparing animal hides for clothing). Human faces and jaws have become smaller in recent human evolution, reflecting the increased tendency for eating softer, more processed foods. Consumption of softer foods and more carbohydrates has also contributed to increase in dental caries (cavities) in recent humans. Patterns of tooth wear are

informative about how people use their teeth. Scanning electron microscopy of the chewing surfaces of teeth reveals microwear patterns relating to diet and tooth use (Teaford, 1991).

Estimating Biological Relatedness: Bone Shapes, Tooth Traits, and Ancient DNA

The shapes and structures of bones and teeth contain key information about population history, since these shapes and structures are at least partly genetically determined. There are some 30 different dental (discrete morphological) traits that are especially useful for identifying inter- and intrapopulation biological relatedness (Scott and Turner, 1997).

Because bone shape is influenced by environmental factors (see above), and many dental traits are obliterated by wear on chewing surfaces of teeth, identification of biological relatedness is sometimes problematic. A potentially more informative approach to reconstructing biological history came about in the mid-1980s with the discovery that DNA is often preserved in ancient bones. The development of polymerase chain reaction made it possible to amplify short segments of DNA into millions of copies that could be used to identify key parts of the genome (O'Rourke et al., 1996; Stone, 2008). The analysis of DNA has allowed the testing of hypotheses about biological history, such as long-standing issues relating to population origins and continental settlement (e.g., the origin of native Americans and migration to the Americas), in ways not possible by study of morphology and traits in bones and teeth alone.

Population Profiles and Demographic History

Physical anthropologists have developed various methods for identifying sex and estimating age at death from skeletons (Ubelaker, 1989). Identification of sex (a biological attribute) allows insight into gender (a social and cultural attribute) and its relationship to health, activity, and social and cultural behavior (Grauer and Stuart-Macadam, 1998). Mortality and fertility history of a past population can be reconstructed from age composition of collections of skeletons from archaeological cemeteries. In a stable population with minimal in-migration or out-migration, age composition is especially informative about birth rates of past populations. A skeletal series having many infants and young children and relatively fewer old adults suggests relatively high birth rate. Conversely, a series containing few children and many older adults suggests low birth rate (e.g., Buikstra et al., 1986). In some regions of the world, the increase in population size that accompanied the shift from foraging to farming appears to be related to decreased birth spacing and increased fertility.

Challenges

Research results derived from the study of ancient skeletons – once mostly relegated to the appendices of obscure, unpublished archaeological reports – are now viewed as integral to archaeology. Reflecting this increased role is the growing visibility of bioarchaeology in the popular press and in the scientific literature. Past human biology provides an essential context for understanding present-day diseases, health, and lifestyle. As the discussion of cultural 'repatriation' continues to build in the United States, Canada, Australia, Israel, and elsewhere, the archaeological community is increasingly called upon to explain to the larger public why ancient remains are important, why they should be studied, and why they are relevant to understanding biology, health, and lifestyle in living people today. Public education about bioarchaeology is important and should be pursued if an informed understanding of the past using the human biological component of the archaeological record is to progress.

Biobanking: Ethical Issues

Abstract

This article outlines the main ethical issues debated in relation to population-based genetic research biobanks. There are many types of biobanking, but few have attracted as much ethical attention as population-based ones. Some possible reasons for this are discussed along with considerations of the political landscape of biobank ethics before the themes dominating the literature are presented: consent to participation; good governance; fairness and reciprocity; commercialization; trust and trustworthiness; and unintended effects such as breaches of confidentiality and privacy, surveillance, and social changes.

Introduction

Many forms of medical research rely on access to various forms of human biological material. For more than a century, it has been common in middle- and high-income countries to gather such material in structured repositories along with information about the person from whom the material was taken. Today such repositories are typically referred to as biobanks. Every day, millions of samples are stored throughout the world for diagnostic, therapeutic, forensic, or other research purposes (*see* Forensic Genetic Databases: Ethical and Social Dimensions). When scholars refer to the *ethical issues* surrounding biobanks, however, they typically refer to a relatively recent and quite specific form of biobanking: population-based genetic research biobanks.

One event, in particular, framed biobank ethics. In 1996 Kári Stefánsson, an Icelandic professor at Harvard University, founded the company deCODE genetics, Inc., and returned from the United States to Iceland proposing the construction of three interrelated databases: a genealogical database, a health sector database of electronic medical records, and a genetic biobank. The genetic biobank was planned to rely on informed consent (i.e., provision of information about the biobank followed by a voluntary signature of consent to participation), but for the electronic patient record to be of benefit to the health services, it would need to include all residents and inclusion could therefore not be optional. Though deCODE would not conduct any genetic research without informed consent, the presumed consent principle for the health sector database was widely misunderstood by international observers as covering all deCODE's research, including genetic research. International ethical commentary on population-based genetic research biobanks became relatively focused on the consent issue, and this interest has in turn affected the reception of subsequent population-based biobanks in, for example, Canada (CARTaGENE), Estonia (Estonian Genome Project), the United Kingdom (UK Biobank), Japan (BioBank Japan Project), and Sweden (LifeGene).

Other major research biobanks existed prior to this wave of activity, in particular in Scandinavia, where central population registries facilitate easy follow-up in cohort studies; but these biobanks were intended primarily for other types of research and only gradually did they become resources for genetic research. Large-scale biobanks are also maintained by military authorities (Eiserman and Castillo, 2000) and the pharmaceutical industry (Lewis, 2004), even though little is known about them and they are rarely granted much attention in relation to the general ethical debate about biobanks. Therapeutic, diagnostic, and forensic biobanks have been used for research, too, but the field of biobank ethics generally concentrates on well-known population-based genetic biobanks. Granted that systematic research on stored human biological material has taken place for more than a century, that other biobanks have long been common but deemed ethically uncontroversial, and that genetic research preceded population-based biobanking, it raises a question: why did the advent of deCODE and other new population-based biobanks in the first decade of the new millennium suddenly raise 'ethical issues'?

There is no easy answer to that question, but it seems that the increase in scale was of some importance. During the 1990s, it became obvious that cohorts needed to be very large to achieve statistically significant results in exploration of genetic dispositions. This implied a transition akin to the one known in physics as the advent of Big Science, when experimental physics necessitated the development of novel forms of collaboration to attract the massive funding needed for the new large-scale experiments (Burton et al., 2009). The increased attention granted by scale interacted with more general public concerns about genetics as well as with related cultural redefinitions of the stored tissue, which now became talked about as 'part of' persons rather than mere 'samples.'

Biobanks did not come with a fine nested set of ethical problems. Diverse groups have negotiated how and why population-based genetic biobanking may constitute ethical problems in reflection of many divergent ideas about what they are, what they should be, and the very point of discussing them. A serious contemplation of biobank ethics must therefore involve reflections on the processes through which ethical problems get named and framed. This article begins with a short reflection of this kind before outlining the issues typically discussed in the literature on biobank ethics.

The Naming and Framing of Biobank Ethics

Ethics, when thought of as an academic discipline, comprises diverse and partly incompatible or at least competing modes of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.82057-7

analyzing moral problems. The ethics literature dealing with biobanks, however, rarely articulates classic differences such as that between utilitarian and deontological positions or between virtue ethics, pragmatic ethics, or feminist ethics. Here, 'ethics' takes a more implicit form as articulation of normative, yet practical, concerns related to the operation and organization of a biobank and its relation to its donating population. Hoffman, Solbakk, and Holm have pointed out how we first need to make sense of biobanks before we figure out what type of problem they might entail. Such sense making usually involves analogies: depending on our chosen analogies, we identify different types of problems (Hofmann et al., 2006). In an analysis of deCODE, for example, Árnason and Simpson showed that when the national media make sense of the company through historical comparisons to the fishing industry, the research endeavor is represented as a contemporary equivalent to well-established Icelandic sources of income: Iceland used to extract natural resources from the sea, and now it is only natural to extract them from the gene pool. The analogy provides the endeavor with enhanced public legitimacy. In other cases, biobanking has been compared with surveillance, whereby biobanks come to represent examples of intrusions of privacy now seen as operating at a genetic level (Williams and Johnson, 2004). Also, analogies are drawn to existing solutions whereby the challenge becomes to align biobanking with standard operating procedures in other settings, such as informed consent procedures used in clinical medicine.

Once ethics develops into concrete suggestions for policies, it also comes to constitute a form of regulation, and as such it interacts with a wider cultural context (Hoeyer, 2005a). Brekke and Sirnes (2006), among others (Hoeyer, 2005b; Metzler, 2010), have argued that biobank ethics entails political consequences by deflecting attention from commercial aspects of biobank exploitation. Biobanking interacts with the cultural context in relation to, for example, the idea of 'genetic exceptionalism,' meaning that everything involving genetics is treated according to its own standards because of popular meanings attached to the word 'gene.' Genetic exceptionalism has been criticized as ethically unfounded, and some have argued that genes are not particularly 'personal' but are shared not only within the family but often across species (Beskow et al., 2001). Still, genetic biobanks have been seen as attracting other regulatory instruments than, for example, nutritional biobanks. Ethicists therefore must reflect on regulatory and cultural implications of their endeavors.

I now turn to what is typically discussed as the ethical issues relating to population-based genetic biobanking beginning with good governance. This is a good place to start because most ethics debates in one way or another feed into thoughts about how one ought to regulate biobanking. Good governance always in some way aims at striking a balance and achieving fairness for the involved actors. The next topic is therefore fairness and reciprocity, followed by an outline of debates of commercial utilization of biobanks, which is a topic deemed particularly controversial and challenging to the aims of fairness. Following the discussion of commercialization, I turn to the issue of trust, which is both represented as a precondition for and an expected consequence of good governance, and something potentially threatened by commercialization. This takes us to issues grouped here as unintended effects comprising concerns that good governance is meant to protect against, but cannot provide guarantees against. I end with the one issue that has gained more attention than any other ethical issue relating to biobanks: informed consent. Informed consent can be seen as the most prominent governance tool in biobank ethics, and I outline the prevailing arguments surrounding this organizational recipe, studies of how it is practiced, and some discussions of its effects.

Ethical Issues

Good Governance

Concrete governance models relate either to the organizational structure, as with suggestions outlining a 'stewardship model' or a 'charitable trust model' (Ashburn et al., 2000; Winickoff and Winickoff, 2003), or to the mode of creating incentives (as with suggestions for biobank impact measurement or taxation of tissue usage; see below). Usually governance models mirror ideals of either universalism or local adaption and optimization. Universalism is more common and occurs in various forms, for example in calls for harmonization to facilitate international collaboration (see, e.g., www.bbmri.eu). The concept of harmonization has also been challenged and accused of covering disagreements between divergent constituencies about what is desirable and of ignoring donor concerns in favor of researcher ambitions (Maschke and Murray, 2004). In the technicality of governance initiatives, basic value differences can be forgotten.

In a reflection on trends and perspectives in biobank governance, Gottweis and Zatloukal (2007) remark that good governance is a response to complex sociocultural challenges and therefore never can be reduced to a technical matter of finding the right tool for the task. Defining the 'good' is basically a normative endeavor. Hume defined public goods as nonrivalrous in consumption and nonexcludable, and this might help us ascertain when a biobank is a 'public good' (Knoppers, 2005); but a definition does not necessarily settle the normative issue of figuring out when and why biobanks produce something desirable, why this outcome is desirable, and for whom. In an attempt to dissect biobanks as public goods, Widdows and Cordell make a distinction between aggregative and corporate community goods, where the former is produced by individuals but compiled by society (as with taxes and government spending), and the latter stems from society and floats to individuals (as with citizen rights) (Widdows and Cordell, 2011). They argue that a community is coproduced with what it perceives as good and in the process of defining the good we seek to identify who shares it. This is also the case with biobanks, they suggest, because biobanks are interesting arenas for public negotiation of value and belonging. Negotiations of contribution (aggregate good) and entitlement (corporate good) become entangled in one another, making it an important task for ethicists to describe the type of community construed through biobanking.

Good governance presupposes a need for identification of the people who should be governed. Ambiguities relate to both users of and contributors to a biobank: are all collaborators of a biobank and the people using the published results biobank

users? Are only the donors, or also their relatives (about whom most biobanks contain information) and other carriers of the same genetic setup, to be seen as research subjects? Should a national biobank consider the interests of all citizens in a given context of collection or limit itself to consideration of the actual donors? Wilson and Chadwick, for example, argue that because biobanks constitute public goods benefitting all members of a society, all citizens are morally obliged to contribute samples to make them as efficient as possible (Wilson and Chadwick, 2007). The difficulties associated with identifying stakeholders appear also when, in the process of establishing good governance, biobankers consider issuing a public consultation. Who, then, is the public? Who should be consulted, and how?

When scholars disagree with Wilson and Chadwick's position, it often reflects contestation of whether or not biobanks really contribute productively to society. Are biobanks *useful* research tools – and for what (Häyry and Takala, 2007b)? Good governance debates therefore involve reflections on what usefulness implies and how it is enhanced in light of very different ideas about what a desirable future holds in store. Debates about usefulness sometimes translate into discussions about incentives for enhancing utility and for sharing biobank resources. Cambon-Thomsen has pointed out how individual researchers who have established biobanks rarely benefit from sharing their material with other researchers, and governance structures that do provide proper acknowledgment therefore need to develop for society to reap the potential benefits of biobanking (Cambon-Thomsen, 2004). Such work, however, builds on the premise that biobanks are worth investing in, and this proposition is contested by researchers thinking that the potential gain from biobanking does not equal the investment (e.g., Watson, 2005). But what constitutes a fair return on a research investment?

Fairness and Reciprocity

Ethical analysis of biobank fairness relates to striking the right balance between state investment and commercial interests (Potts, 2002), or striking a fair balance in relation to what donors get in return for their research contribution. The latter is discussed in the form of both benefit sharing (sharing of medical or commercial benefits) and feedback of research results. Since the ethics debate is heavily centered on the relationship between donor and research institution, I too will focus on the latter set of issues here.

Two competing ethical frameworks construe the relationship between donor and biobank very differently partly because they, as discussed above, view the potential benefits of biobanking differently: Either the donor is seen as deprived of profit in analogy to a Marxian 'exploited worker' (Corrigan and Williams-Jones, 2006), or the citizen who opts out of biobanking is described as a 'free rider' scrounging on the community biobank (Eriksson, 2005). Obviously, the two frameworks construe the biobank community differently. If we limit ourselves to the relationship between actual donors and the biobank and begin with fairness reached through feedback of research results, some scholars have argued for a right to know about research results in general as well as specified individual feedback (Fernandez et al., 2003); while others have argued that unwarranted individual feedback could undermine donor interests and cause insurance complications and unnecessary worries, and that feedback of aggregate research results could hamper donor anonymity and cause public confusion through dissemination of unvalidated propositions (Renegar et al., 2006). Even if it is accepted that a biobank does have a feedback obligation, it remains unclear *how* to deliver feedback without turning it into an obligation on behalf of the donor to keep him- or herself informed; just as it remains undecided which pieces of information will be relevant for whom (Knoppers et al., 2006): Feedback might very well deliver knowledge that is still too uncertain to be of clinical value, and it might relate to susceptibilities that the individual prefers not knowing.

Feedback constitutes a form of direct benefit sharing through which donors are expected to achieve fairer treatment. The sharing of benefits can also be construed as a natural consequence of societal progress, whereby the key ethical issue becomes one of establishing criteria for 'progress': Do biobanks enhance human health, or do they consume resources with little prospect of substantial medical benefit besides, perhaps, more individualized treatment options available mainly for those whose health needs are already well attended to? To deal with these issues, one must contemplate the range of the biobank constituency and its diverse interests *prior* to actual biobank research. Another way of construing benefit sharing relates to the potential sharing of profit (rather than medical benefits), which becomes an issue *after* biobank research has proven a success, also in commercial terms.

Hayden has argued that ethical emphasis on benefit-sharing programs reflects an urge to break with superficial portrayals of 'altruistic donations,' which serve to cover up donor exploitation; but she also points out that such programs represent a form of politics that might generate effects other than the desired 'fairness' (Hayden, 2007). She claims that benefit sharing as a form of politics creates new collectives of those identified as entitled to a share; but also that risks, not only benefits, become shared in new ways because the terms of research participation become construed as a matter of individual negotiation. Furthermore, when putting emphasis on benefit sharing, biobanks might make potential donors think of research participation as a future source of income despite the very limited chances of such profits ever materializing.

Commercialization

The role of the private sector in relation to population-based genetic biobanks is highly controversial for reasons other than just benefit sharing. In some cases, such as UK Biobank, there is an emphasis on the national in the rhetoric used to mobilize donors, an emphasis that is seen by some as at odds with downstream commercial appropriation and patenting of research results (Busby and Martin, 2006) (*see* Anthropology, Genomics, and Human Variation: National Roots). Commercial usage of biobank resources places emphasis on the creation of marketable research results, such as diagnostic tools or pharmacogenetics, potentially at the expense of public health research into prevention or health promotion.

Commercialization is related to a set of legal issues with ethical repercussions having to do with entitlements to

donated tissue. As a general rule, the human body and its parts cannot be bought and sold as plain property. Ownership is therefore not an appropriate category to describe entitlements to tissue. Still, stakeholders may claim a range of other entitlements such as the right to give an informed consent, dispositional rights, rights of utilization, and so on. When the sample leaves the donor, it is typically construed as fully beyond property rights, but further down the line biobank materials may give rise to patentable knowledge that is appropriated by researchers, research institutions, or collaborating companies. In most instances, the actual legal entitlements to donated tissue are quite ambiguous, with several competing stakeholders regarding themselves as having the ultimate dispositional rights concurrently. Some scholars have viewed the incremental downstream commercialization as illustrative of a more general 'commodification of the body'; while others find such concerns misplaced and suggest providing donors with straightforward property rights (see Wilkinson, 2003). Individual property rights to one's body are also seen by some legal scholars as a means for protecting donor privacy (Laurie, 2002), a route that has been criticized by philosophers for misconstruing the key values associated with privacy (Ursin, 2010). Though ideas about commodification might not stand closer analytical scrutiny, strong moral ideals of the separation of bodies and commodities reflect a set of societal values that ethical analysis must also take into account when assessing the stakes in biobanking, in particular if biobankers want to conserve the public trust needed for their endeavor.

Trust and Trustworthiness

O'Neill has pointed out the need to make a basic distinction between trust and trustworthiness (O'Neill, 2002). A biobank may very well be surrounded by trust without deserving it, and it might act honorably and trustworthily without actually being trusted by donors. From a philosophical perspective, she finds it more useful to discuss criteria for trustworthiness than for the existence of 'trust' as an empirical phenomenon, and yet trust continues to receive more attention in biobank debates than trustworthiness.

Trust is discussed both as a means for biobanking and as a desirable end in its own right (Caulfield and Outerbridge, 2002). Trust is an elusive concept. From a sociological perspective, Luhmann argues that trust is a prerequisite of modern times where familiarity is no longer possible in our everyday operations (Luhmann, 2000). As a necessary mechanism in complex networks, trust implies an element of calculated risk that the confidence it expresses might be unfounded. It is often said that there is a 'crisis of trust,' and the concept has also been used in relation to biobanks, but one might also say that biobanks as large-scale, anonymous, and open-ended social networks produce the very sort of social relation in which trust in the sense described by Luhmann emerges. Petersen has argued that claims of a biobank 'crisis of trust' hinge on an illusion of some undefined historical era in which everybody trusted biobankers (Petersen, 2007). There is no reason to assume that it ever was the case, and without any clear measures of trust it is hard to say whether there is less or more of it today. The Eurobarometer surveys indicate that more people are becoming aware of biobanks, and the countries in which most people know about biobanks are also the countries in which biobanking has caused public controversies and gains the highest support. Based on these findings, Gaskell and colleagues argue that perhaps public controversy creates public trust, rather than eroding it, by creating general awareness of biobanking (Gaskell and Gottweis, 2011). Breaches of trust can ensue from breakdowns in confidentiality or abuse of information (Sutrop, 2007), or stem from mismatches between donor expectations and biobank practices, for example with respect to the issues of commercialization mentioned above or the type of disease investigated, which takes us to the issue of unintended effects.

Unintended Effects

Trust can be said to be unfounded if a biobank leads to unwanted, unintended effects. Such effects are what good governance should protect against, and ethicists have pointed to potential dangers relating to risk and safety; breaches of confidentiality and privacy; surveillance; and social implications relating to identity, stigma, and group membership.

Risks associated with biobank research participation are different from those typically in focus in clinical medicine. The living body faces little or no physical risk because the research is done on stored samples (Eriksson, 2005). The major risks are informational in nature, rather than physical, and they therefore reflect the potential harm accruing to the individual through breaches of confidentiality. Such breaches can be analyzed as causing harm if they affect the individual's chances of health insurance, employment, or even marriage. They can also be seen as interfering with the right to privacy. From the latter perspective, it is not the harmful effect as such constituting the problem; it is the violation of intrinsic values relating to human life (using deontological rather than utilitarian premises for the analysis). Not all languages have any word corresponding to the English 'privacy,' and a pan-European project on the protection of privacy in biobanking found considerable cross-national variation in the values attached to a private life, integrity, and intimacy (Taylor and Townend, 2010). Accordingly, different donors will define breaches of privacy differently, and good governance must take specific local approaches in reflection of the prevalent concerns in the concrete biobank context.

One way of protecting donor privacy is through anonymity, but for biobanks to be effective it must be possible to link up samples with registries continuously over time. Hence, protection of privacy comes at a cost of utility. Furthermore, a sample cannot be fully 'anonymized' in as far as it always contains unique biological information, and therefore the merit of anonymization policies as such remains disputed. Also, it has been pointed out that it is sometimes possible to identify otherwise anonymized individuals in published articles through their unique single nucleotide polymorphisms (SNPs) (Homer et al., 2008; Lin et al., 2004).

Social scientists have pointed to unintended effects operating at social levels besides those mainly affecting individual donors. Biobanks could be associated with potential increases in surveillance, for example in conjunction with criminal investigations or public health monitoring or for commercial

purposes. Any increase in available information involves increases in potential oversight and data mining for purposes other than the intended. Besides surveillance, social scientists have discussed how biobank data may generate new genetic identities, reshape group affiliations, and challenge established conceptions of ancestry (Prainsack, 2007; Tutton, 2004). If conditions relating to sexuality, mental state, or behavior become redefined as genetically determined, it may affect how they are perceived and thereby their potential for stigma and/or public acceptance. Genetic research sometimes challenges oral stories of descent, and in some contexts indigenous ancestry is associated with particular legal entitlements making genetics politically hazardous for donors (Reardon, 2005). In short, research participation may have so-called looping effects for identity, entitlements, and societal groupings; and individuals may thereby also facilitate research having unintended effects for people other than the donors who provided their informed consent in the first place.

Consent

Nevertheless, informed consent is beyond a doubt the topic that has been most intensely debated in relation to biobanks, and thereby also the governance tool most commonly suggested as a solution when addressing the various problems (or potential problems) listed above. Informed consent involves full disclosure of relevant aspects of the planned research and voluntary cognizant consent from the research subject. Because population-based genetic biobanks usually work as long-term cohort studies, people donate to a research facility that is expected to run for 10, 30, or 50 years or even longer, and to outlive individual donors and researchers. It is very difficult to predict the type of research that will be deemed most valuable in 30 years, but it is reasonable to say as much as very few people hope it will be the same as today. Research is expected to create new questions. If donors are to be informed about the exact nature of the research they facilitate with their donation, they either have to renew their consent continuously (and perhaps bequeath this right to relatives upon their death) or the biobank value must be seriously reduced. Biobanks therefore have to decide the level of specificity in the information sheets used during the consent process, and it has given rise to an intense debate about the pros and cons of specific versus general consent as well as whether a general consent can be said to be informed at all (Diest and Savulescu, 2002). Also, because genetic traits are to some extent shared, it is discussed whether it is the individual, the family, the community (geographical or disease specific), or the nation who should consent. Such issues have caused a multiplication of concepts (e.g., group consent, community consent, broad consent, soft presumed consent, open consent, general consent, and alternatives such as written authorization). Topics such as proxy consent for minors and incapacitated adults are known from other areas of research, but they have also been treated in relation to biobanks where inclusion in a biobank cohort may take place at birth but not necessarily be followed up with confirmation at the age of majority (Hens, 2010; Samuël et al., 2008). Instead of ensuring consent to a researcher-defined agenda, others have suggested focusing more on genuine donor influence on the research, for example through deliberative democracy models (Secko et al., 2009) or by emphasizing participation rather than consent. Following the latter inclination, it has been suggested to avoid talking about donors and instead think of the people delivering material as ongoing research participants and co–decision makers (Tutton, 2007).

The intense debates about consent (or participation) tend to focus on *what* to do, rather than the ethical reasons *why* it should be done. Is consent desirable because it allows people to follow their personal preference, because it provides the means for individual protection against harm, or because it facilitates desirable relations between researcher and research subject? Often, it is said simply that informed consent serves to protect respect for autonomy, while the concrete meaning of autonomy is left undefined (Häyry and Takala, 2007a). Ethical analysis serves an important purpose in identifying confusions of this sort and helping the involved actors realize their own stakes and values.

Numerous studies have shown that in actual practice, donors do not remember or understand the information provided, and even when they do it rarely relates to the issues they find most important (e.g., Barr, 2006; Ducournau, 2007; Hoeyer, 2003; Skolbekken et al., 2005). The prospect of continued consenting has stimulated terms such as 'consent fatigue' (Cambon-Thomsen, 2004). Also, the emphasis on consent has been criticized for sidestepping values of solidarity (consolidating the before-mentioned free-rider problem) and for practical reasons for hampering good research and adding to the cost of administration (Furness and Sullivan, 2004). Certain discoveries could not have been made had researchers not been allowed to go back and use old samples to identify disease agents that no one would have considered including in an information sheet at the point of sample collection.

Conclusion

Do informed consent practices enhance good governance? There is no way to reach agreement on that issue when it is raised as a simple yes or no question, even though it is an observable fact that such hopes have been attached to the informed consent ideal. Instead, ethical analysis of population-based biobanking must move beyond simple 'what should we do now' questions and allow time to reflect on basic quandaries such as 'who are part of that "we"' and 'what is good' for those involved in and affected by biobanking. Biobanking has become a way of negotiating boundaries for communities and for reflecting on the direction of contemporary medical research. This article has outlined some of the topics through which such negotiations manifest themselves, namely, in debates about public goods, fairness, forms of commercialization, criteria for trustworthiness, and potential unintended effects. Answers remain to be found, and they must be argued in relation to the specific contours of concrete biobank initiatives.

Biocitizenship

Abstract

Biological or genetic citizenship is a term used to describe the complex intersection between novel developments in the life and biomedical sciences, the growing involvement of lay citizens in scientific research and health activism, the formation of individual and group identities organized around a genetic or biological classification, and the reconfiguration of the political economy relating to health care provision, as well as the generation of wealth and health from living processes.

In 2008, Roger Cooter (2008) described biological citizenship or biocitizenship as a keyword-in-the-making since this term seemed to emerge in tandem with the phenomenon it sought to describe. As with many keywords in the social and natural sciences, this term was developed almost simultaneously by different authors: Adriana Petryna (2002) in her monograph titled *Life Exposed: Biological Citizenship after Chernobyl*, by Deborah Heath et al. (2004) in their essay titled "Genetic Citizenship," and by Nikolas Rose and Carlos Novas (2005) in their essay titled "Biological Citizenship." These different renderings of what can be termed biocitizenship share an interest in exploring the complex intersection between the life sciences, citizen activism, health and social welfare provision, the regulation and governance of life, and the broader political economy. This article begins by exploring biocitizenship through exploring how the aforementioned authors discuss the relationship between biopolitics and biological or genetic citizenship, the intersection between identity practices and biologization, the political economic relations informing this conception of citizenships, and the role of information and communication technologies (ICTs) in shaping this form of citizenship.

Biopolitics and Biocitizenship

As the terms biological and genetic citizenship are oriented toward charting and describing novel developments in the life sciences, the transformation of health care systems, and the forms through which biomedical research is conducted, they are in effect concerned with examining biopolitics and the government of life in the contemporary present. In the case of the Ukraine, as Petryna (2002) explains, the state, failed both intentionally and inadvertently to produce knowledge about its population that would enable the state to provide for the welfare of its individual citizens and population in the years following the Chernobyl nuclear accident. Petryna's explanation focuses on the state's shifting field of medical categorizations relating to radiation sickness, and its uncertain criteria for compensating those affected by this disaster. Given this context of uncertainty and unknowability in post-socialist Ukraine, for Petryna (2002), biological citizenship is about the efforts of citizens to use their embodied experiences, their suffering, and their acquisition of biomedical and legal knowledge to create social welfare institutions that not only benefit those affected by radiation exposure, but much more broadly, to provide for the health and well-being of this population.

Heath et al. (2004) also draw analytically on a version of biopolitics in their elaboration of genetic citizenship, focusing in particular around struggles regarding the provision of health and social welfare to United States citizens. Although the bulk of their ethnographic analysis focuses on the efforts of genetic advocacy groups, scientists, clinicians, and legislators to transform the organization of health care and the biomedical research establishment around rare diseases in the United States, they reference the important role of the AIDS and women's movement in transforming the institutional and therapeutic modalities through which life is governed in this particular national context. For Heath et al. (2004), biopolitics is not simply a matter of the state, but includes health activists, physicians, politicians, scientists, and nonhuman actors such as genetic databases and bioengineered medical devices as part of what they term genetic governmentality.

Rose and Novas' (2005) account of biological citizenship also seeks to extend the analytical purchase of biopolitics by attempting to describe how citizenship projects have been linked to beliefs about the biological existence of humans as individuals, as a population, and as a species. In contrast to Petryna (2002) and Heath et al. (2004) whose work focuses on the Ukraine and the United States, Rose and Novas (2005) employ the term to discuss the intersection between biology and citizenship in the history of European and North American state formations. The authors build upon Michel Foucault's (1978) account of biopolitics by emphasizing that biological citizenship has individualizing and collectivizing facets. It has an individualizing dimension in the sense that individuals in the past and in the present use medical and genetic knowledge to understand and shape certain aspects of their selves. It is collectivizing in the sense that biological beliefs about the human species and 'races' in the past served as a means to differentiate and exclude certain groups of citizens. As Rose and Novas (2005) briefly discuss, biological citizenship in the early part of the twentieth century assumed a racialized form in Europe, North America, South America, and Australasia. For Rose and Novas (2005), the eugenics movement provides one exemplar of biological citizenship as it sought to act upon the biological characteristics of citizens and populations in the name of racial purity, mental hygiene, the elimination of 'undesirable' genetic diseases, and the augmentation of public health using a variety of compulsory or voluntary measures

 http://dx.doi.org/10.1016/B978-0-08-097086-8.85059-X

depending on national context. Shifting to the present, Rose and Novas (2005) argue that biological citizenship does not assume a nationalized or racialized form, but is collectivizing in the sense that biological understandings can form the basis for a shared identity around a particular genetic or chromosomal abnormality, that may lead to the formation of organizations oriented around challenging medical expertise or that seek to promote greater medical research on a particular genetic condition.

Identity and Biocitizenship

A defining feature of biological citizenship is the claim that new connections are being forged between biology and identity. Building upon Paul Rabinow's (1996) concept of biosociality, biological citizenship makes reference to the growing role of patients' organizations and health-based social movements in contemporary biomedicine. In the case of Rose and Novas (2005), as well as Petryna (2002), they put forward the claim that the types of relationships being forged between identity and biology are distinct from those organized around the eugenics movement in the early part of the twentieth century, which were based on ill-founded conceptions of human genetics and race. A notable difference from the past, as these authors suggest, is that the association between identity and biology is said to give rise to illness-based social movements. As Petryna (2002) points out in her work on the case of post-Chernobyl Ukraine, suffering, in both its biological and social sense gave rise to legitimate claims on the state for medical care, for health care reform, for scientific research, and for democratic political reform. For Rose and Novas (2005) the link between identity and biological citizenship refers to the organization of collectivities around a biological conception of shared identity; collectivities who work to gain specialized medical knowledge about their condition, advocate for greater research funding for their illness, create novel communities of support through Internet forums and Web sites, and seek to develop novel modalities of patient participation in medical research. Heath et al. (2004) understand the ties between identity and genetic citizenship to be located at the multiple intersections of embodied experience, genetic difference, and practices of care associated with political activism, coalition building, and participatory knowledge making.

Economies of Life: The Political Economy of Biocitizenship

In Petryna's (2002) ethnographic account of post-Chernobyl Ukraine, the economic hardships faced by this emerging democratic nation-state had an impact on its health care system and policies regarding compensation for those affected by radiation sickness. As Petryna (2002) documents in her study, the individual and collective survival strategies of biological citizens to seek compensation for their injuries takes place in a context where basic survival is at stake and in conditions of economic and social exclusion.

In their rendering of genetic and biological citizenship, Heath et al. (2004) also are concerned with mapping the novel economic relations emerging at the intersection of health activism and the life sciences. This also is the case for Rose and Novas (2005). Heath et al. (2004) document how the health advocates they studied often had to form complex political economic relations with the state and the market in order to gain access to medical treatment, to ensure the provision of social services, and to further biomedical research on rare orphan diseases. The forms of the activism of such genetic advocacy groups are engaged in often transcend the boundaries of a single genetic condition, and are oriented toward imagining 'other possible futures' and an 'ethics of care' in US public discourse.

In their account of biological citizenship in the contemporary present, Rose and Novas (2005) argue that is oriented around the generation of biovalue, a term that they borrow from Catherine Waldby (2000). According to Rose and Novas (2005), advances in molecular biology and biomedicine, alongside the development of national biobanks in the early part of the twenty-first century make it possible to harness the blood, tissue samples, and health data of national populations, in order to generate potential revenue streams for biotechnology companies, in addition to possibly augmenting the health of national populations. For Rose and Novas (2005), an animating feature of what they term a 'political economy of hope' is that the generation of biovalue extends to patients' organizations who, through the establishment of blood and tissue registries, are able to generate economic returns in the form of patent royalties, and, as in the case of PXE International, health benefits through the development of diagnostic techniques or therapies. And, lastly, this political economy of hope generates novel ethical values regarding the participation of patients in biomedical research.

Biocitizenship and Digital Life

Another theme that unites accounts of biological (Rose and Novas, 2005) and genetic citizenship (Heath et al., 2004) is the emphasis accorded to the role of ICTs in enabling socially diverse and geographically dispersed persons affected by genetic disease to share life experiences, to provide social support to one another, to disseminate biomedical knowledge, to engage in participatory knowledge making, and lastly, to coordinate advocacy efforts. The Internet not only is a tool used for communication among patients and families affected by genetic disease; it also facilitates cooperation with clinicians and scientists, and can be used as a marketing tool through which pharmaceutical and biotechnology companies engage with a diverse range of audiences.

Abstract

Bioethics is a relatively young field of learning drawing on many established academic disciplines, such as philosophy, jurisprudence, sociology, life sciences, and others. Bioethics is concerned with genuine problems from philosophical ethics as well as practical questions arising from the medical and nonmedical life sciences and affecting public policy and the direction and control of science. This article aims at providing an overview on the meaning and scope of bioethics, the history of bioethics, the international and intercultural dimension of bioethics, the contribution of related disciplines, and major substantive issues in bioethics – such as decisions at the beginning and end of life, allocation of resources, and moral problems connected to research in life sciences.

The History of Bioethics

Bioethics is a relatively young field of learning drawing on many established academic disciplines, such as philosophy, jurisprudence, sociology, life sciences, and others. The main stimuli for the increase of research in bioethics around the 1960s arose from the technical progress in medicine, societal changes in the western world, and a revitalized interest in the discipline of philosophical ethics (Jonsen, 2003). Around that time, progress in medical technology – e.g., kidney dialysis, artificial respirators, organ transplantation, medically safe abortions, and the contraceptive pill – radically changed the practice of medicine and created the demand to apply ethical reasoning to concrete situations. In addition, the first steps toward a powerful gene technology were made. Roughly at the same time, profound changes occurred in western societies. The civil rights movements in the United States and elsewhere, as well as the transformation of traditional institutions such as the family and the church, caused moral questions concerning an individual's rights and duties in modern society. These developments were accompanied by a rising concern about humanity's impact on the world sustaining us and the future generations, leading to the development of new subspecialties of bioethics such as animal ethics and environmental ethics.

Finally, the philosophical discipline of ethics received a fresh impetus. For a long time, there had been consensus among most philosophers that judgments about moral problems could not be rational in principle. In the second half of the twentieth century, much work has been done, which successfully aimed at providing scientific methods for moral reasoning (Arrington, 1997; Stingl, 1997). In combination, these developments formed the basis of the extraordinary rise of bioethics in the second half of the twentieth century. Meanwhile, bioethics has become institutionalized in academic departments, professional journals, and international associations.

The Scope of Bioethics

Although medical ethics remains to be the most known feature of bioethics, the latter has a broader scope and is understood to encompass questions arising in the context of the life sciences, that is, medicine and the biological disciplines, as well as in some fields of the environmental and social sciences.

The scope of bioethics can be divided roughly into three fields of research. First, there is the project of a rational justification of moral norms. It forms the methodological core of bioethics, since it supplies the strategies of moral reasoning that are applied to the respective problems at issue.

Second, there is what might be called clinical ethics; this group encompasses moral problems that individuals, for example, nurses, physicians, or researchers, are confronted with in their daily practice. Examples of this kind involve decisions about the end of life, for example, decisions regarding abortion or physician-assisted suicide.

Finally, there is a group of problems that should be dealt with on the regulatory or policy level. Examples of problems of this kind involve the necessity to develop operationalizable juridical guidelines for awarding patents on biological materials, policies for the allocation of medical resources, or social challenges from neuroenhancement use of the animals for medical purposes or access to the benefits of the advancement of science and technology.

The Method of Bioethics

Morality and Philosophical Ethics

The task of professionalized ethics is not to be seen in gaining insights from some special source of knowledge – insights that would entitle the ethicist to demand a certain course of action or insist on certain conduct being prohibited. Rather, the proper task of ethics is the critical assessment of existing moral convictions and norm systems established from them. This assessment should be done by using a method that is in principle accessible to everyone. Moral convictions are subject to such an assessment when they generate conflicts, for example, when they are incompatible with other moral convictions. In the case of moral conflicts there is a need for an ethical criterion that allows us to establish which conviction should be followed. A simple example for such a criterion is the 'Golden Rule': "We should do unto others as we would wish them to do

unto us." This rule does not provide us with a material action-guide, but provides a formal criterion that any action guide has to fulfill in order to be morally acceptable.

Traditionally, it has been the domain of philosophical ethics to design strategies for the solution of moral conflicts. In this sense bioethics is only a new area because the conflicts to be solved were unknown until progress in medical technology and societal changes directed public attention to the ethical problems of the life sciences.

It should be the role of a philosopher wishing to contribute to the solution of bioethical issues to provide a clarification of the moral concepts involved and to reconstruct the arguments used in the discussion. On this basis he can develop strategies of moral reasoning that help determine which moral convictions one ought to accept.

It should be made clear, however, that these strategies are developed on the basis of an underlying ethical theory and that a variety of different ethical theories has been developed during the history of ethics (for an introduction, see Frankena, 1973): consequentialism claims that, if anything determines the moral status of an action, then it is the consequences of that action (Singer, 2011). Contractarian theories analyze what it means for a society to endorse principles of fairness and justice (Daniels, 2008). In revitalizing ancient approaches, virtue ethics aims at developing action guides that tell agents what they ought to do in concrete situations (Pellegrino and Thomasma, 1993).

Principle-based approaches hold that some general moral norms are central to moral reasoning; contrary to this (Beauchamp and Childress, 2013), case-oriented approaches advocate starting with the examination of concrete cases and proceeding from that to more general norms (Jonsen and Toulmin, 1990). An example of the latter is the ethics of care: it aims at an expressly practice-oriented approach to bioethics by engaging emotionally in the moral problems at issue (Gilligan, 1982). The above list of ethical theories is neither complete nor does it present a proper classification of such theories, but it names some of those theories most relevant in the recent debate on bioethics.

Such theories often share certain presuppositions, for example, the demand for 'universalizability' and 'consistency,' but differ in others, so that – depending on the theory applied – different strategies of moral reasoning can be developed in the discussion of a certain moral problem at issue.

It is often used as an argument against the use of moral reasoning for practical questions that there are no indisputable ultimate arguments for moral norms achievable on a rationally understandable basis. Although true, this should lead to modesty, not resignation, concerning the power of moral argumentation, since we should not demand in the field of ethics what is not available in other areas also: for example, in applying the laws, a judge is always left with a degree of discretion within which he has to examine carefully the special circumstances of the case at issue.

The ability to analyze the moral concepts involved and to apply one or the other ethical theory to bioethical problems will help the physician, policy maker, or whoever else is confronted with these questions to think about them in a sophisticated way and to develop moral convictions acceptable to all parties concerned.

Bioethics and the Natural and Social Sciences

The methodology supplied by philosophical ethics is only one, albeit essential, component in the attempt to solve bioethical problems. The philosopher is trained in examining the arguments proposed, whether they are valid relative to some standards of rationality or whether they fall back upon metaphysical or emotion-based beliefs. Substantial arguments about bioethical problems should be based, however, on knowledge from those sciences in the domain in which those problems originated. A discussion of the ethical problems of genetic counseling, for example, without the participation of physicians and others involved in this counseling would be futile. Similarly, it would be pointless to establish the impact that the results of a new technique, such as the genetic manipulation of food, will have on society without the participation of those social sciences that have the necessary empirical methods at their disposal. Finally, it would be vain to develop recommendations for societal regulations, for example, economically effective and juridically sound allocation procedures for medical resources, without the backing of health economics and jurisprudence. Bioethics is embedded in an inter- and transdisciplinary context and supports the discussions of other scientific disciplines and politics. Moreover, it helps to raise public awareness, social involvement, and democratic governance of the further development of science and technology.

The International and Intercultural Aspects of Bioethics

The experience of a conflict between existing moral convictions in view of the consequences of new techniques is not confined to any cultural or geographical frontier: it is a universal experience. The actual object of the conflict, however, may be highly dependent on, for example, the culture in which the conflict arises – examples are the debates on whether informed consent to, say, research participation must be given strictly by the (autonomous) individual concerned, or can be replaced by family or community consent, or the controversies on just benefit sharing in exploiting bioresources around the globe.

This context dependency of bioethical problems is often taken as the prime argument against there being a single method of bioethics, since solutions to moral problems are – so it is claimed – valid only relative to the particular situation for which they were developed. But, although it is often the case that material moral convictions do differ between cultures, this does not in itself exclude the possibility of there being a formal criterion acceptable across cultures – in the same way that the differing views of the plaintiff and the defendant do not in themselves exclude the possibility of an acceptable judgment.

Major Issues in Contemporary Bioethics

The sheer number and variety of issues discussed in contemporary bioethics compels us to make a rigorous selection. The following section throws a spotlight on some topics that were intensely discussed in recent debates and that furthermore aptly illustrate an interdisciplinary approach to bioethics (see Chadwick, 2012; Kuhse and Singer, 2006; Post, 2003).

Medical Ethics

Since the time of Hippocrates and the ancient Greek medico-philosophers, the emphasis of medical ethics has been on the doctor–patient relationship. Since the 1960s, this has been debated mainly in terms of the improvement of patient autonomy in view of an allegedly prevailing paternalism on the physician's side (Katz, 1984; Faden and Beauchamp, 1986). Today medical ethics has developed into a highly differentiated research area with rich conceptual debates, for example, on the meaning of human dignity, as well as thoroughgoing analyses of structural changes in medical practices and of new medical technologies for the sake of solving existing and avoiding future moral conflicts. Topics of ongoing debate are among other moral problems arising at the beginning of life, the end of life, clinical practice, and the allocation of resources in and to the health care system, access to health care, biobanking, and organ transplantation.

Beginning of life

The moral acceptability of abortion as well as the fate of handicapped newborns is one of the most extensively and intensely discussed issues in bioethics. Basic to this discussion is what quality an entity must possess in order to be a moral subject endowed with certain rights, for example, a right to life, and how we know when an entity actually possesses this quality.

For some authors, this quality is simply that of belonging to the species *Homo sapiens* – a position called speciesism and criticized because affiliation to a certain biological class is seen as morally irrelevant as the affiliation to a certain race, nation, or social class.

According to another position, this quality is that of being a person– where being a person is usually understood to involve some kind of self-consciousness. A third position claims that being an agent, that is, causing one's own actions, makes an entity a moral subject. Characteristic of the latter two positions is that, according to them, there is the possibility that some members of the species *H. sapiens* are not persons or agents (e.g., a human fetus) while some persons or agents are not members of species *H. sapiens* (e.g., gorillas or dolphins). Once what counts as a moral subject has been defined, it still has to be clarified what rights this moral subject is endowed with. It is, for example, not plausible to claim that a fetus is endowed with an absolute right to life, when even adults are usually not awarded such a far-reaching right: for example, in the event of war and in self-defense (Tooley, 1972).

Over and above this, some criterion has to be found which is applicable in practice and which allows us to determine whether an entity belongs to the class of moral subjects or not. Here an interdisciplinary approach is necessary that combines the above moral considerations concerning the quality characterizing a moral subject with the state-of-the-art knowledge from the natural sciences about when an entity actually possesses this quality.

End of life

It is widely accepted today that patients have the moral right to refuse medical treatment even if this may result in their death. In some cases, patients not only refuse further treatment but explicitly want to end their life. Even if there is no consensus on the moral evaluation of suicide, there is widespread understanding and legal toleration when patients commit suicide as a radical means for ending what they deem to be intolerable suffering. It is controversially debated, however, whether a physician may assist a patient in committing suicide (physician-assisted suicide) or even actively bringing the patient's life to an end (euthanasia). It has long been (and still is) a rule of most professional codes in medicine to forbid active euthanasia, whereas passive euthanasia is sometimes allowed. This distinction between a morally reprehensible action (active euthanasia) and a morally acceptable action (passive euthanasia) is based on an alleged moral difference between 'killing' (act) and 'letting die' (omission). There have been numerous attempts to point out the morally relevant differences between these – without much success so far (Steinbock and Norcross, 1994). Although active euthanasia may under certain conditions be acceptable from the point of view of ethics, academic as well as political and public debates on this issue remain controversial. Only very few countries, for example, the Netherlands, have legalized active euthanasia. The reason for this might be that performing (or even only advocating) active euthanasia can jeopardize the patient's trust in his doctor and the health-care system.

Another controversially debated topic in bioethics is the brain-death criterion: modern medical techniques allow us to sustain the blood circulation of patients, who could not breathe spontaneously due to the loss of certain basal brain functions. According to the traditional definition of death – the standstill of the cardiovascular system – these patients are not dead (although they depend on the continuous support of a respirator). On the one hand, these patients have warm bodies and rosy skin, like a sleeping person, and unlike a corpse, on the other hand, they are irrevocably unable to show any behavior expected from a 'normal' living human being. Since the traditional death criterion was deemed to be inconclusive and unsuitable for medical practice a new criterion was developed. The Ad Hoc Committee of Harvard Medical School to Examine the Definition of Brain Death in 1968 developed the brain-death criterion from which modern procedures for determining brain death are derived. It is important, however, to notice that the brain-death criterion is not the only possible definition of death – indeed the traditional criterion of complete cessation of blood circulation is another one. In a certain sense, death is not naturally given but defined by convention.

Clinical Practice

The interaction of patient and doctor (and other health care professionals) undoubtedly forms the core of medical practice. A salient feature of this relation is that the health care professional due to his training and experience has knowledge that the patient usually has not. It is especially the professional experience that allows the medical professional to collect and interpret a multitude of parameters relevant for evaluating a patient's situation, and for making suggestions for her treatment. Moreover, any patient is for the health professional one out of many (severely) ill patients he has to professionally take care of. For the patient, however, her (severe) illness frequently constitutes a crisis radically changing her life. These at first only

descriptive differences in knowledge and judgmental capacities are interpreted differently in view of their normative implications and precipitate in different conceptions of the patient–doctor relation – a frequently used scheme is the differentiation between a paternalistic model, a contract model, and a partnership model (Emanuel and Emanuel, 1992). These models are used, for example, in the debate on medical paternalism, that is, the question whether a doctor or other health care professionals are morally justified to limit a patient's freedom of decision for the sake of the patient's well-being (Katz, 1984).

Further moral challenges are caused by structural changes in the health care system. The traditional ideal of a doctor–patient relationship, where the doctor commits himself exclusively to his patient is hardly realistic under the conditions of modern health care systems. Doctors as other health-care professionals are part of complex institutions such as hospitals and have, therefore, obligations, for example, toward their employer or the health insurance of their patients – that may be in conflict with the aim to provide the best health care for the patient.

Finally, as research in medical ethics differentiates increasing attention is paid to the specific needs and vulnerabilities of patient groups such as minors, and the mentally ill. A core problem in these groups is that the now commonly accepted duty to respect a patient's autonomy is not easily applied in patient groups whose capacities for autonomous choice are limited or even not existing (Bloch and Green, 2009).

Allocation of Resources

Whenever limited resources are allocated (rationing), refraining from taking desirable actions of one kind becomes the price of performing actions of another kind. Health care is no exception to this universal truth. Fixing a budget in the health-care sector means that an increase in spending for, say, preventive medicine has to be accompanied necessarily by decreasing spending in another sector, say, transplantation centers or, on another level, higher spending in a state's education or military sector necessitates lower spending in other sectors, for example, the health system. The lack of even a basic public health-care system makes allocation of resources to the health care system an important topic in many developing countries. But increasing costs of health care have brought the topic of allocation of resources in the health-care system onto the general agenda even in those countries that are equipped with a public health-care system. The moral questions arising from this are among other things: if, as it widely accepted, there is a human right to health care, what has to be provided by the state: a decent minimum or optimal provision? Who shall allocate the scarce resources and by what criteria? Is there a moral obligation to redistribute health-care resources on a global level (Daniels, 2008)?

Human Nature: Understanding and Intervening

Medical innovation without research involving human subjects seems hardly possible. Much research is done in test tubes, cell cultures, and in nonhuman animals, but at least clinical research investigating effectiveness and safety of medical innovations in human subjects is without alternative. Moreover, using nonhuman animals for medical purposes is burdened with scientific and moral challenges: scientific, because the transferability of results gathered in nonhuman animals such as rodents to humans is limited; moral, because inflicting suffering and death on nonhuman animals for human purposes is itself contested (Sandø and Christiansen, 2008).

Fundamental for performing research in human subjects is that the test person has given her informed consent (Berg et al., 2001). Over and above the controversies on the adequate conceptualization of 'informed consent' and its application in the practice of research, even more complicated challenges arise when it comes to research in patient groups such as minors and the mentally ill whose capacity for informed consent is frequently limited. Another vulnerable patient group is, for example, that of pregnant women and their fetuses. Where in the past decades the common view was that vulnerable populations are best protected from harm through research by excluding them from risky clinical research, it is now increasingly argued that this restrictive practice bears the danger of depriving vulnerable populations from research-driven medical innovation.

Ethics of Genome Research and Manipulation

Human genome research – best known via the International Human Genome Project, but actually consisting of a multitude of different research programs – has experienced an extraordinary boom during the past decades. Although this research provides promising unprecedented options for the prevention, diagnosis, and therapy of diseases, this bears considerable risks. In this context it is useful to differentiate medico-technical problems of human genome research (e.g., the safety of gene therapy protocols) from moral problems (e.g., the moral acceptability of intervening into the human genome). Only the latter will be considered in the following.

Genetic tests performed before and after birth as well as the genetic screening of populations are debated controversially because of the potential misuse of the information acquired. Even if the test is used only for medical purposes, the results might lead to stigmatization and discrimination of individuals or ethnic groups. Although not based on the state-of-the-art knowledge from the biomedical sciences, this geneticization of medicine should be countered by very careful implementation of genetic diagnostics in the medical practice, including a stronger than usual emphasis on the protection of the privacy and autonomy of the tested (Buchanan et al., 2000).

Another possible domain of use of genetic diagnostics is the testing of individuals applying for insurance coverage (Sorell, 1998): it is feared that individuals with an increased genetic risk might have to pay higher premiums or, worse, might be unable to obtain insurance coverage at all.

It is hoped that the incorporation of human or nonhuman genes in body cells (somatic gene therapy) or the human germline (germline gene therapy) will be a major contribution to the therapy of diseases with a genetic component – hereditary as well as nonhereditary. Somatic gene therapy is seen as a relatively unproblematic method from the ethical (not medico-technical) point of view, since the transferred genes are not inherited by the descendant of the treated individual.

In stark contrast to this, germline gene therapy is controversially debated. Since the transfer of genes to germline cells affects all offspring, the question arises whether such an intervention in the genetic constitution of an unborn individual can be legitimated and, on a more general level, whether germline therapy leads to a new form of eugenics or genetic enhancement. Since most authors hold that if germline gene therapy were to be applied, it cannot be exclusively confined in the long run to medical application; the debate, therefore, centers on the question whether the intervention into the lives of future persons by genetic enhancement is different in any morally relevant way from classic interventions such as education (Agar, 1998; Habermas, 2003).

The first cloning – i.e., asexual reproduction – of a mammal in 1996 raised moral questions concerning the application of this technique to nonhuman animals and humans (Harris, 1997). Animal cloning is debated mainly in view of the legitimation of manipulating the genome of wild-type animals and the effect of a change in the genetic pool of the biosphere that might have considerable effects on biodiversity.

The debate on human cloning has focused on the ethical problems of producing copies of existing human beings (reproductive cloning). Concerning reproductive cloning, the emphasis of the moral debate lies on whether there are morally acceptable aims for the actual application of this technique, whether the genetic identity of a clone and its donor amounts to a morally problematic personal identity, and whether human cloning leads to an infringement of the dignity of the clone or the donor.

The cloning only of parts of humans (cells or organs) is technically still in its infancy but successful cloning of human cells has been performed leading to pluripotent stem cells. This has caused an intense debate concerning the moral status of the embryonic cells (see Lauritzen, 2001).

Neurosciences

Rapid advance in the neurosciences over the past decades has not only greatly improved our understanding of the brain function and disease, but also created new powerful means for modulating brain function. Examples for the former are among other imaging techniques, neurogenetics and computational models of the brain. Prominent examples for the latter are techniques such as deep brain stimulation and also psychotropic drugs.

These developments reactivated debates on the fundamental relation of mind and brain, for example, on whether the mind can be reduced to, or is noting else than the deterministic brain function (Bennett et al., 2009). Related are debates on the justification and exact meaning of concepts like 'free will' and 'moral responsibility.' Far from being theoretical only these debates may have implications for education, and the law, especially, the penal system (Illes and Sahakian, 2011).

Another area arousing great interest in both academia and the general public are attempts to not only restore restricted brain function, but to improve brain function beyond the normal. This neuroenhancement raises questions on what 'normal' means, and whether and to what extent it may be justified to change the normal human nature that hitherto was largely something humans had to accept as given, and not something that can be changed by them. In a radical form support for enhancing human capacities leads to transhumanism, that is, the program of not only pushing human capabilities to their natural limits, but of dissolving these limits themselves, that is, of transcending human nature (Hansell and Grassie, 2011).

Animal Ethics

The debate on the moral status of nonhuman animals and the moral boundaries of using them for human purposes has become a prominent topic in bioethics over the decades. Challenging in this context is not only the way we treat those animals (primates and dolphins) that possibly have higher mental capacities in some respects akin to those humans have, but also the conditions for using animals for food production, and for research purposes.

Central to animal ethics is the debate on what moral status animals do have: according to some authors it is some kind of higher mental capacity that conveys moral status to certain animals. According to another position, it is not higher mental capacities that only very few animals possess likely, but the ability to suffer which seems to be widespread in the animal kingdom. Further arguments tie the moral status of animals to their having specific needs or simply to the fact that they are living organisms.

Besides these attempts to clarify the foundations of animal ethics, the practice of using animals for human purposes finds increasing interest in academic moral discourse as well as in public debates. Topics among others are the moral implications of industrial livestock farming, that is, the justification of customizing animals using classical breeding methods and gene technology for production needs and consumer preferences. In this context ethical questions on, for example, 'naturalness' and 'integrity' as moral criteria for establishing moral boundaries for the intentional manipulation of life forms are raised. In addition, risks for biodiversity and the stability of ecosystems are discussed. Another hotspot of animal ethics is the concern with using animals for purposes of medical research (Sandø and Christiansen, 2008).

Synthetic Biology

Synthetic biology is a young and dynamic branch of modern biology that focuses on understanding the conceptual design of living systems. What makes up the specific difference between classic molecular biology and synthetic biology is debated, but in a first approximation synthetic biology in contrast to molecular biology aims at changing organisms by redesigning large parts of them, or even by introducing entirely new functions. In a radical form synthetic biology is aiming at creating new, that is, synthetic life forms. On the application level synthetic biology is hoped to facilitate the search for new effective medicines, cheap biofuels, and new methods to produce petrochemicals. The salient challenges of synthetic biology are biosafety and biosecurity risks. The biggest problem in the assessment of biosafety risks of synthetic organisms is their strong divergence from well-known natural systems. When there is no natural reference system, many proven methods of technology assessment are not applicable (Gutmann, 2011). The de-skilling agenda of synthetic biology

and the possibilities of dual use also lead to enormous biosecurity risks, since states, or terrorists may exploit synthetic biology for hostile purposes.

Abstract

The history of bioethics is closely related to that of genetics and genomics. As genetic issues have moved out of the clinical setting and become increasingly concerned with genomics, biobanks, and public health, there has been a move away from the primacy of individualism and autonomy to include a focus on other bioethical principles such as solidarity and the common good.

Introduction – the Relationships between Bioethics and Genomics

The development of bioethics has been closely connected to that of genetics and genomics, at least for parts of their respective histories. The history of bioethics in relation to genetics and genomics has been marked by varying emphases, at different times, on environmental and biological explanations of human health and behavior, and by changing perceptions of the relationship between the individual's interests and the public good. Thinking about the ethical issues in genetics of course preceded the development of bioethics as a field of study. Thus in the early years of the twentieth century, in relation to the sterilization of Carrie Buck, it was claimed "three generations of imbeciles are enough" by the judge in the case of *Buck v Bell*. The history of eugenics in the early twentieth century, and responses to that, had a significant influence on how debates became framed in the second half of the twentieth century, in particular in relation to the emergence of the nondirective ethos in genetic counseling. Reaction against forced sterilization of those deemed 'unfit,' such as Buck, led not only to concerns in succeeding decades about the improper interpretation of scientific information, but also to worries about abuse of genetic science; to an emphasis on free choice in the genetics clinic; and a preference for environmental explanations and interventions at a social level. In the second half of the twentieth century, however, in the light of the success and high profile of genetic and genomic research, genetic explanations and promises regained popularity.

Bioethics came to prominence as a distinct field in the 1970s. Although there are some differences of opinion about its origins, the first use of the term is frequently attributed to Van Rensselaer Potter, who used it to refer to issues relevant to the biosphere as a whole – in other words, including concern for environmental as well as biomedical issues. In its earliest manifestations in the 1970s, however, it was primarily concerned with relationships between health care professionals and individual patients, and with allocation of resources in situations of scarcity, such as the allocation of new technologies developing at the time, including dialysis machines. Reacting against the perceived paternalism prevalent in the professions, and reflecting social changes at the time such as civil rights, feminism, and a liberalization of laws relating to homosexuality and abortion, an individualistic ethic predominated, with autonomy as a central ethical principle. Toward the end of the twentieth century, however, bioethics expanded its scope of concern. This coincided with rapid developments in genomics, and with the initiation and progress of the Human Genome Project (HGP), which allocated a dedicated budget to address ethical, legal, and social issues (ELSI). This was followed by an ELSA programme (ethical, legal, and social *aspects*) in Europe. Although ELSI and ELSA have become recognized as brands in themselves (subsequently succeeded by Responsible Research and Innovation), the broader field of bioethics was also itself greatly affected by the huge explosion in work on the ethical dimensions of genomics. Bioethics, according to the definition of the International Association of Bioethics, examines not only ethical, legal, and social issues but also philosophical ones, and thus includes considerations of the philosophical aspects of identity, for example, which have also been at stake in debates about genomics.

Over time, the issues giving rise to the most scrutiny in bioethics and genomics have changed, as genomics has moved out of the clinic and into society at large. What have also been noticeable are the ways in which scientific developments have posed challenges for ways of thinking about bioethical issues such as informed consent, leading to a considerable amount of work on ethical frameworks (Knoppers and Chadwick, 2005).

Issues in Clinical Genetics: Genetic Testing and Counseling

When the focus of discussion was within the genetics clinic, and concerned with diseases recognized as having an identifiable genetic component – for example, Huntington's disease, the ethical issues turned largely on the autonomy and confidentiality of the client in relation to testing, which may be diagnostic of a current condition or predictive of a late onset one, and relating not only to adults but also TO their children and fetuses. In the clinical context a genetic *test* (as opposed to *screening*) is typically carried out where there is some reason to think there may be a problem. A good example is the situation where there is a strong family history of breast cancer. For adults, it has been argued that there is a right not to know (see below) the result of a predictive test which reveals a risk factor but not certainty about onset or severity of a disease.

Where children are concerned, for parents with a child with an apparent disorder, the result of a *diagnostic* test may bring relief in knowing what is wrong. In the case of prenatal testing,

however, there might be difficult questions concerning termination decisions, in cases where a fetus is found to be suffering from a genetic or chromosomal abnormality (relevant factors also include the context of social support, or lack of it, for persons with disabilities which might affect a mother's decision). Preimplantation genetic diagnosis and embryo selection avoid the issues of termination of a fetus but the issues of the criteria for selection of embryos, resource issues, and what should be done with 'spare' embryos remain controversial.

Nondirectiveness

As mentioned above, following the abuses of genetics in the early twentieth century and the rise in individualism in medical ethics and bioethics, the prevailing ethos in counseling was that of nondirectiveness, facilitating but not directing the decision of the client in relation to decisions such as termination. Nondirectiveness may of course be difficult to achieve, in situations where there is a power differential between counselor and client; and some clients may actually want to be directed or at least advised, but for present purposes the main point is that the ethos reflects the primacy of autonomy.

In some situations, there is a clear tension between the interests of the client and those of third parties. Some of the most discussed questions in the early 1990s concerned possibilities of disclosure to family members of the results of genetic tests on blood relatives, and the conflict between the interests of those family members and the confidentiality of the person tested – for example, is it right to disclose a finding of non-paternity where a genetic test on the fetus reveals that the mother's partner could not actually be the genetic father? The balance between competing interests here is normally struck by the position that individuals should be encouraged to share their information, but that there may be some cases at the extreme, where disclosure is permissible.

Children

The genetic testing and screening of children is acknowledged to be a special case. In relation to children, the issues of autonomy are more complicated, where it might be the parents' wish to have a child tested, because *they* want to know. The possibilities of stigmatization and self-fulfilling prophecy are real issues for a child who is symptom free but identified as being at risk of a late onset disorder. Hence there are strong arguments for the view that children should not be tested for late onset disorders until they are capable of deciding for themselves whether or not to be tested. The situation is different where there are potentially life threatening or life limiting disorders which can be treated in childhood, where the expectation would be that parents should opt for treatment as they would with any other illness.

Genetic Exceptionalism

The fact that blood relatives may share genetic predispositions to particular diseases was one of the principal factors driving discussion of the thesis of 'genetic exceptionalism,' the thesis that there is something special or different about the ethical issues in genetics, the other factors being that genetic information is predictive and independent of time: hence a test in childhood has the potential to reveal an individual's risk status with regard to certain late onset diseases. The thesis of genetic exceptionalism, however, has been criticized on the grounds that other types of medical information may share these features in varying degrees: although the ethical issues in genetics may be particularly complicated, they are not in a wholly different category from those relevant in other areas of medicine, so that there is no need to develop a bioethics specific to genetics per se. Different issues need to be considered on their own merits and in specific contexts.

While the issues in clinical genetics and genetic counseling remain live, they are no longer the primary focus of concern or debate in bioethics. What has changed is that genetic information has become relevant not only in the genetics clinic but throughout medical practice, as the biological factors underlying not only genetic disorders but also the common diseases such as heart disease and the cancers are identified. This is perhaps one of the most marked changes in relation to genetics – the 'geneticization' of health and health care.

Screening

In contrast to genetic testing, where there are factors relating to an individual which suggest that testing is indicated, a screening program is carried out on a population where there is no reason to think, for any given individual, that he or she is at higher risk (Nuffield Council on Bioethics, 2003a). In the 1990s there was considerable discussion about the principles underlying the introduction of a genetic screening program – adapting the 1968 Wilson and Jungner principles, for screening in general, to the particular context of genetic screening. The first criterion is that the condition screened for must be important, or serious; another is that there must be an acceptable treatment – which was changed in the genetic context to 'scope for action,' as the intervention in question may be a termination or change of lifestyle. There was considerable but to some extent inconclusive discussion about what constituted a condition sufficiently 'serious' to warrant a screening program. A classic example is phenylketonuria, for which newborns are screened and which can be controlled by a diet low in phenylalanine.

There have been cases of interventions at the population level to counteract high incidence of genetic disease, for example, in the case of thalassemia in Cyprus. The prevention program changed over time with developing technologies, but in 1980 premarital screening was made compulsory by law. The incidence of thalassemia has declined and patients with the condition have a better life expectancy as treatment improves. This example makes clear, however, that genetics retains its connection with reproduction decisions of those who may be themselves unaffected, but carriers, and is not only concerned with individuals who either have a condition or are diagnosed as being at risk.

Gene Therapy

One of the reasons why issues in genetics have been so high profile lies in the nature of genetic disorder and the options for

treatment. It is in the nature of genetic disorders that they cannot typically be cured in the way that infectious diseases can, for example, by prescribing drugs (notwithstanding the current anxieties about antibiotic resistance). The boundary between genetic and nongenetic disease is not, of course, clear cut: infectious diseases have a genetic component, not only in relation to the genome of the infecting organism but in its interaction with the genome of the persons affected. People will differ in their susceptibility and response to infectious disease in accordance with their own genomic variation.

The early prospects of gene therapy, of introducing a functioning gene into the body of a patient who lacked a functioning one, by using a vector such as a virus, led to disappointment arising partly from the results of tests and partly because of ethical concerns about some trials. The focus of interest turned away somewhat to the new promise of stem cell therapy. In the twenty-first century, however, some forms of gene therapy are seeing encouraging results. In January 2014, for example, positive news was reported in relation to a trial using gene therapy to treat eye disease. There remain concerns about the difference between somatic gene therapy (where the new genetic information affects the individual patient only) and germline therapy (where the germline is also affected). In the latter case, future generations will be affected who have no opportunity to consent. To some, however, the latter argument is overstated, as we cannot avoid decisions that will affect future generations in any case.

Debates about clinical genetic testing, screening programs, and therapy, however, were overtaken by genomics moving center stage with the advent of the HGP.

The HGP and Genomics

The aim of the HGP was to produce a complete map and sequence of all the genes in the human genome, so genomics marked a shift of attention from genes to genomes. Until quite recently most of the bioethical discussion related to genomics concerned the nuclear genome, which was what was referred to in the HGP. The sequencing of the mitochondrial genome, completed in the 1980s, passed almost unattended by any ethical comment. presumably because of how the role of the mitochondrial genome, which exists within the cell outside of the nucleus, was perceived. The analogy of a battery has been used, suggesting that the role of mitochondria is just to provide energy to the cell, in contrast to the nuclear genome which, together with other factors, influences the characteristics of the phenotype.

It is nevertheless the case that a defect in the mitochondria, which are inherited through the female line, can have a devastating effect on the phenotype. The battery analogy, however, has been influential in making the positive case for mitochondrial replacement therapy, which involves removing the diseased mitochondria from a woman's egg and replacing them with those from donor. The egg can then be fertilized by the woman's husband or partner. This has been described in some sections of the press as producing babies with three parents, but the supporters of the technique argue that it prevents potentially very great suffering by the prevention of mitochondrial disease which cannot otherwise be cured.

With regard to the nuclear genome, it was thought by some that to know the genome of an individual would enable us to know everything about that person – that a human being was identified with the sum total of his genome. Genetic determinism, the thesis that a person's genes determine the outcome in the phenotype, had considerable support. It therefore came as a shock to some when the HGP was completed and revealed that there are far fewer genes in the human genome than had previously been thought – about 22 000 rather than 100 000. This led to the claim that genetic determinism was dead. If there are so few genes in the human genome, genes cannot possibly explain the huge variety and complexity that we see in human beings. Genetic *factors*, as opposed to whole genes, are clearly influential in relation to development and phenotypic expression, but so are many other factors, such as gene–environment interaction, copy number variation – variation in the number of copies of a genetic factor that an individual has – and epigenetics, or factors over and above the genome that affect gene expression.

Biobanks

In addition to trying to make sense of the information provided by the outcome of the HGP itself, attention turned in the last decade of the twentieth century to population wide genomic research (Gottweis and Petersen, 2008). Biobanks were established in a number of countries, such as Iceland and Estonia. The purpose of a biobank was to collect both DNA samples and phenotypic information from participants, in an effort to establish links between genetic factors and the development of disease, and not only diseases classifiable as 'genetic diseases.' For example, the UK Biobank aimed to clarify the factors at work in the common diseases that typically manifest themselves in midlife, such as heart disease and the cancers.

Attention turned to the study of variation in the genome – the ways in which individuals differed from each other at the genetic level, leading to effects which may be due to a single base pair in a particular part of the genome. There had been earlier interest in variation, in the Human Genome Diversity project, but that had attracted considerable amount of hostility among different ethnic groups who had concerns about the motivation behind the study of diversity.

Biobanks, particularly in Iceland, were also initially very controversial and gave rise once more to discussions about whether there is anything special about the ethical issues involved. One prominent example concerned informed consent. The doctrine of informed consent had become a cornerstone of biomedical ethics in the twentieth century, following not only the concerns about eugenics mentioned above but also malpractice in relation to research subjects, such as had occurred both in Europe in World War II and in the United States.

Participants asked to donate DNA samples to biobanks were asked to give their informed consent. The problem that emerged was that it was not always clear what they were being asked to consent to. Biobank operators were proposing to collect and store their samples, but for what? It might not be clear even to the scientists and researchers what they might want to do with the samples a few years down the line. New

scientific discoveries would almost certainly reveal new lines of inquiry. Thus it was argued by some that genuine informed consent could not be provided in relation to a donation to a biobank. Again, this did not support a thesis of genetic exceptionalism, because there is a view that fully informed consent is an ideal that can never be fully reached in any branch of medicine. The new context, however, gave rise to the bioethical debate about the difference between 'narrow' and 'broad consent.' A person who gives narrow informed consent agrees to specific, detailed research purposes, whereas broad consent involves agreement to research for purposes that may not be specified or specifiable at the time. The UK Biobank adopted a form of broad consent, asking participants to consent to being in the Biobank – or not.

There are different arguments in favor of broad consent in the biobank genomics context. First, the purposes for which biobanks are established are clearly to some extent undermined if there are restrictions on the research that may be done on the samples. This is not just an argument about scientific freedom: it is argued that this kind of population research is essential for future population health, in addressing the incidence of the common diseases. Another argument is that the kind of harm which may befall contributors to a biobank is very different from that involved in conventional medical research such as a drug trial. The physical intervention involved is limited to the taking of a blood sample: the potential harm arises largely from the potential from access to and misuse of a participant's information, especially if the samples are linked to phenotypic information of various kinds.

As noted above, in the clinical genetics context confidentiality and disclosure had been an issue. Biobank research however gave rise to a considerable amount of new debate about the handling of genomic information, both as regards storage and access. Storage issues included to what extent and in what ways samples were linked, or not, to phenotypic information, by techniques of coding and anonymization. If samples could not be linked at all, then the value of the research was decreased. On the other hand, the greater the possibilities of identifiability, the greater the risk to the privacy of the individual participant. Increasingly it was realized, in any case, that where DNA samples are collected and stored the possibility of maintaining complete privacy is undermined, and it was argued by some that the better course would be to acknowledge this fact. This led to a call for 'open consent' where participants would donate in the knowledge that there was no guarantee of privacy, in the interests of research.

The development of biobank research and population wide genomic research has been associated with a move toward an emphasis on public health in bioethics, marking a widening in scope of this field, although it would not be accurate to say that bioethics had no public health aspect at the beginning, as resource allocation issues constituted a driving force behind its development. It would be a mistake to characterize the issues here as a trade-off between a personal interest in privacy on the one hand and a public interest in health on the other: there is also a public interest in the maintenance of privacy protections, and the balance of interest has to be negotiated.

Nevertheless, given the predominance of the public good argument in relation to biobanks, it is not surprising that there has been a shift in the bioethical framing of the issues. In addition to the arguments for broad consent, there has been a move toward a greater emphasis on principles other than the individualistic ones at play in the earlier days of bioethics, including equity and justice. Another obvious example is the principle of solidarity, which has been appealed to in this context. The principle of solidarity, which has been defined in the report prepared by Barbara Prainsack and Alena Buyx for the Nuffield Council of Bioethics on solidarity (Prainsack and Buyx, 2011) as the willingness to bear costs for another's good, can be used, for example, to provide a reason for contributing to a biobank. Autonomy nevertheless remains important – the individual must be free to give consent, whether broad or narrow, but other principles are increasingly emphasized.

Feedback and the Right (Not) to Know

Much of the discussion over genetic testing and screening concerned an individual's right to access to and control over their genetic data. The ways in which this played out in the clinical context of genetic counseling have already been alluded to.

In the biobank context, these issues took on a particular focus in relation to feedback of results of biobank research. Opposing arguments have been advanced in relation to this on the one hand it is argued that participants should not be given information other than the general results of the research. In many cases, the raw data that emerge will not be meaningful to individuals in any case. On the other hand, it is argued that if information specific to an individual (sometimes called incidental findings) emerges which could be relevant to their health, even potentially life saving, then there is an obligation to tell them. At the time of writing this debate is far from resolved, and there are ongoing debates about what information participants in biobanks and genomic research should have access to.

Debates in the 1990s had already considered whether there could be a right not to know genetic information (Chadwick et al., 2014). The historical predominance of autonomy, choice, and informed consent in the second half of the twentieth century perhaps produced a default position that individuals had a right to information: what had to be justified was withholding it. Different understandings of autonomy, however, suggested that an individual can make an autonomous decision to live their life without certain information which might not only cause distress but undermine their conception of themselves and their life plan.

Personalized Medicine

The potential irony in the situation where principles such as solidarity and concepts of the common good are appealed to in the ethical discussions of population wide genomic research, is that the interest in the variations in the genome between individuals, the discovery of which was an aim of this research, was to drive the quest for a new form of individual-centered medicine, so called personalized medicine, whereby treatment could be prescribed in accordance with the particular genome of the patient.

The argument for personalized medicine made much of the fact that traditional medical practice and drug prescribing had a considerable problem of disease caused by medical examination or treatment, or iatrogenic disease. There was a large burden of not only morbidity but also mortality arising from the side effects of pharmaceutical products. While it was known that any given drug would not be appropriate for every individual, in the past for the most part the only way to find out would be for that individual to take the drug – a trial and error approach predominated in prescribing. The theory behind pharmacogenomics was that it should be possible through genomic research to discover the associations between genetic factors and drug response. Implementation in clinical practice would of course have to have access to genetic information about the individual patient, and this would then inform the choice of drug, or the appropriate dosage. The promise was safer and more effective medicine – and also a reduction in time wasted through trying drugs that did not work for a given patient (Nuffield Council on Bioethics, 2003b).

The label 'personalized medicine' has not proved totally beneficial. First, it is not always clear what 'personalization' means. Initially personalized medicine might have meant assigning patients to groups of good or poor responders to a particular drug on the basis of a targeted test – a fairly limited sense of personalization, which might more appropriately be called patient stratification. Developments in science and technology, from genome-wide association studies to next generation sequencing, have given a new meaning to personalization, ultimately involving investigating the whole genome sequence of an individual. (Some approaches to personalized medicine also include wider ranges of nongenetic data; e.g., NAS, 2011; ESF, 2012). The metaphor of 'tailoring' has been used to describe the fit between the individual's genome sequence and the prescription of medical and lifestyle advice. The cost for such sequencing has also fallen rapidly and continues to fall.

There are also new challenges, however. While on the one hand, it fits into an individualistic paradigm in society that employs the rhetoric of choice, this has also led to one of the main criticisms: that on a wide scale it is only feasible in wealthy societies (despite the falling costs). Indeed, it has been called 'boutique' medicine by Abdallah Daar and Peter A Singer (Daar and Singer, 2005). They claimed, that the underlying research could be beneficial for other purposes – what has been described as 'drug resuscitation' of products taken off the market because of adverse events in the west, to help underserved populations in developing countries, where differences in genomic factors might avoid the adverse effects. This discussion is part of a much wider debate about the sharing of the benefits of genomic research. Benefit sharing, to be understood in a wide sense beyond commercial benefit, has become a standard ethical dimension of proposals for genetic and genomic studies, one that points to the greater consideration of the equity and justice (HUGO, 2000).

Direct-To-Consumer Testing

Following the HGP companies emerged offering testing direct-to-consumers, where the findings could include information about genetic ancestry, and health-related information. As regards the latter they gave rise to many concerns about the bypassing of professional counseling and advice in the delivery of the information, as well as criticisms regarding the accuracy and usefulness of the information provided. Whereas some people regarded it as an aspect of the 'democratization' of science to facilitate this kind of accessing of their genomic information, there were worries about the possible adverse effects of individuals acting on misleading information about themselves and their families. In December 2013 in the USA, for example, the Food and Drug Administration ordered the company 23andMe to halt its disclosure of health-relevant results to new direct-to-consumer testing clients.

'Recreational' and Behavioral Genomics

While the main argument for genetic testing, screening, and now sequencing has always been the medical benefits, other uses have increasingly become apparent, some of which are regarded as recreational. Ancestry tracing has already been mentioned. Behavioral and forensic genomics raise ethical issues about responsibility, freedom, and punishment – could there be a legitimate defense in court relating to one's genetic predisposition, for example. Also giving rise to concern are the promotion of tests related to character and natural talents of children, and to pick out budding sports stars so that they can be given appropriate training. In some cases this overlaps with medical matters, as in the case of a predisposition to sudden cardiac death which is clearly important for someone considering a sporting career. The main issues here, however, remain the quality of the scientific basis of the information on offer and the tension between the marketplace and the professions as the medium through which genetic information should be conveyed or bought and sold.

An area which also crosses boundaries is that of nutrigenomics. At first sight it seems analogous to pharmacogenomics. Just as the latter facilitates personalized prescribing on the basis of genetic information, so the former, in principle, makes possible personalized dietary advice which can also be extremely important in the health care setting, especially in the light of a purported obesity epidemic. However, nutrigenomics is very different from pharmacogenomics in that foodstuffs, with multiple ingredients, are far more complex and work on more aspects of the body than do drugs, which are designed to act on specific targets and pathways in the body. Establishing the associations on the basis of which useful advice can be given is therefore more challenging.

Genomics and Identity

The ethical debates about genetics and genomics have raised identity issues in a number of ways. First, there has been considerable controversy about what counts as a disorder. This is of course a live issue even absent the genetic element: mental disorders are a case in point, and testing for predisposition to such disorders is particularly sensitive. In the genetics clinic the question of what counts as a disorder has been a particular issue because of the fact that termination was one potential outcome of prenatal genetic counseling, giving the impression

that the birth of babies with disabilities was regarded as an outcome to be avoided. Disability rights groups objected to the identity and worth of people being reduced to a disorder, questioned the very label of disorder, and feared the return of a form of eugenics. Arguments on the other side attempted to draw a distinction between the conditions and the people who experienced them: between discrimination against a disorder and discrimination against persons with disabilities, with varying degrees of success.

For a given individual or community, the results of genomic research can disturb long-held beliefs about their ancestry or relatedness, leading to considerable distress and upset in some well-publicized cases, such as that of research on the Havasupai Indians, who gave consent to the use of their samples in research on diabetes, which was a serious problem in their community. However, they subsequently learned that their samples had been used to study other things, and that publications on the results contradicted their history as they saw it and a lawsuit led to the payment of significant compensation.

Another identity issue concerns that of the human species as a whole. Although the majority of the ethical writing concerns human genomics, the genomes of other species have been, and continue to be sequenced, with results about the number of genes in some of those species that have been surprising to some. Information about both the complexity of the genomes of other species and their degree of relatedness to the human has the potential to undermine some long-held beliefs about the identity of the human species in relation to those others.

International Perspectives and Cultural Issues

International issues in genomics may take different forms – first there are questions both ethical and practical about international research and the transfer of samples and data across borders – issues of ownership are at stake here in both subnational research projects and national initiatives. Whereas biobanks were initially set up in different countries such as Iceland and Estonia, as mentioned above, arguments for linking between different national efforts appeal to the need for large amounts of data to underpin statistical validity.

The second type of international issue, which is related to the first, concerns cultural differences in various parts of the world where not only ethical values but also the cultural meaning of genetic material may be different. In these situations ethical principles may at least need to be revisited, and informed consent may need to be approached in different ways. Public engagement has become increasingly important, partly as a necessary condition of a process of benefit sharing. The Human Heredity and Health in Africa initiative (H3Africa), for example, which includes a number of different genomics projects funded by the Wellcome Trust and the National Institutes of Health in the US, is addressing issues of public engagement and informed consent in multiple populations in different social contexts, both rural and urban.

In terms of international approaches to the issues in genomics, these include declarations such as the Universal Declaration on the Human Genome and Human Rights issued by UNESCO (UNESCO, 1997), which states in Article 1 "The human genome underlies the fundamental unity of all members of the human family, as well as the recognition of their inherent dignity and diversity. In a symbolic sense, it is the heritage of humanity." While this Declaration lays down universal principles, other international instruments incorporate rules. At the level of the European Union, for example, the proposed new Regulation on Data Protection lays down parameters for transfer of data across the Union and beyond.

Conclusion

Despite the close interaction between bioethics and genomics, and the ways in which bioethical principles have been subject to reinterpretation in the light of the new challenges, issues are far from settled. The ways in which bioethics has been done have also changed during the period, to include much more empirical research and reflection on modes of multidisciplinary working. The rapid advances in technology and prospects for implementation offer the promise of considerable development in the relationship between science and bioethical debate in the years to come.

Abstract

Bioethics is a rapidly developing field. It draws on conceptual and methodological tools from a number of academic disciplines to tackle ethical issues that arise within medical practice, the life sciences, health care provision and management, and related areas. From its early inception in the form of medical ethics, where it was mainly concerned with moral conflicts that played out within the relationship between doctors and patients, it has evolved into a multidisciplinary field that utilizes a wealth of theoretical and methodological approaches to address a variety of moral and practical questions. This article focuses on the most recent developments of bioethics in the so-called postgenomic age.

Introduction

Bioethics is a rapidly developing field. It draws on conceptual and methodological tools from a number of academic disciplines, including philosophy, sociology, theology, jurisprudence, psychology, and others, to tackle ethical issues that arise within medical practice, the life sciences, health care provision and management, and related areas. From its early inception in the form of medical ethics, where it was mainly concerned with moral conflicts that played out within the relationship between doctors and patients, it has evolved into a multidisciplinary field that utilizes a wealth of theoretical and methodological approaches to address a variety of moral and practical questions. These range from purely theoretical philosophical work, to various types of empirical studies, to endeavors to influence and shape practical policy making. This article will focus on the most recent developments of bioethics in the so-called post-genomic age; for a description of the field of bioethics as such, its history, and the development of its scope throughout the twentieth century, see the cross-references at the end of this article.

There is no coherent use of the term 'postgenomics.' One common use refers to a cluster of research areas that were spin-offs of the Human Genome Project (HGP). In the late 1990s, the US-led yet international HGP set out to identify all genes on the human genome, to determine the sequence of the base pairs that make up human DNA, and to render this information available to the international research community. A draft sequence of the first human genome was published with much media fanfare at the dawn of the new millennium.

Another use of the term reflects some of the insights following the HGP and the subsequent changes to the field of genetics. Although the human genome sequence published initially was incomplete and riddled with problems and open questions that scientists are still struggling to solve, the inherent promise of the completion was that humans could now understand the basic units of life and would soon be able to develop new disease treatments. Many of these expectations have turned out to be unrealistic. While the HGP has doubtlessly triggered an unprecedented advance in the development of high-throughput tools in molecular biology, the capacities for interpreting these data and for making sense of what they mean for health and disease lag behind. One of the biggest lessons learned in the aftermath of the HGP was that the information that can be obtained from DNA sequence information alone is seriously limited (Maher, 2008). Researchers have therefore started to move beyond studying the sequence of nucleotides on the human genome (structural genomics) toward understanding their function (functional genomics), gene expression under various physiological states (transcriptomics), and modifications of the genome (epigenomics). They also look at processes within other areas of human biology, and how they intersect with our DNA. For example, researchers in proteomics study the structure and function of proteins, those studying metabolomics focus on substances and processes involved in metabolism, others look at the interaction between proteins and other molecules ('interacteomics'), and others study the interactions of humans with their gut microbial flora ('microbiomics'). The suffix '-omics' signifies that substances and processes are not studied individually, but at a large scale, often using mass spectrometry tools. For example, in proteomics, although the function of proteins and their interaction with other molecules may be looked at in particular individuals, the aim of the field is to learn about the role of proteins in human organisms in general.

The exact meaning of the term 'postgenomics' also depends on the discipline and institutional context of its use. In its widest meaning, the term 'postgenomics' comprises endeavors to understand the function of DNA in the context of other molecules; in this understanding, anything that moves beyond mapping the structure of human genomes is included. This means that all '-omics' disciplines, including the use of environmental (e.g., phenotypical and lifestyle related) data to refine and complement biological '-omic' data, are included in this concept. In this article, the term 'postgenomics' is used in this wide sense.

Changes in Methodological Approaches

In its early days, bioethics relied heavily on using theories and arguments from the fields of theology, anthropology, law, and, in particular, philosophy. Indeed, for a long time, many viewed bioethics as a subdiscipline of philosophy that applied philosophical theories such as utilitarianism, virtue ethics, deontological theory, or a set of midrange principles to bioethical

questions (often called the 'applied ethics approach'). Until the early 2000s, the methodology chapters of many bioethics textbooks focused on these and a few other philosophical approaches (such as feminist philosophy, political philosophy, or care ethics theory). Other theories and methodological approaches were referred to only briefly, if at all. This has changed over the last two decades. With the discipline growing in size as well as in academic and political relevance, it began to draw in people from more diverse academic backgrounds, which in turn has contributed to the inclusion of a wider range of concepts and theories. The following section will give a brief overview of the most prominent expansions and additions to bioethics' theoretical toolbox.

At least for the last decade, the social sciences have played an important role in bioethics (Fox and Swazey, 2008). With the growing need for both hard and soft law and policy and regulation of bioethical issues that lie outside of clinical medicine, the legal, social, and political sciences have increasingly contributed important theoretical and empirical work to bioethics. They have done so both by theorizing governance and regulation and through the development of practical policy proposals using methodological tools from their respective theoretical background, such as the analysis of cases and judgments (Mason and Laurie, 2010), or policy and contextual analysis (Gottweis and Prainsack, 2006; Moreno, 2012). Moreover, psychology has informed recent bioethical work more explicitly than in the past, for example on coping with illness, on the role of carers, or within neuroethical debates (see, e.g., the journal *Philosophy, Psychiatry, & Psychology*). Economics has also contributed to the growing body of bioethical theory. Health economists have long been in dialogue with ethicists about issues of allocating health care resources, such as the construction, application, and consequences of cost–benefit analysis (see, e.g., Nord, 1999). More recently, behavioral economics – itself drawing on psychological research – has introduced the concepts of 'choice architecture' and 'nudging' as factors that powerfully contribute to shaping our decision making (Thaler and Sunstein, 2008), which have been taken up vigorously, for example, in public health ethics (see, e.g., the UK's Centre for the Study of Incentives in Health).

Due to their disciplinary origins, these and other recent theoretical contributions to bioethics bring with them particular terminologies and traditions, and this can sometimes lead to translational misunderstandings. The multi- and interdisciplinary dialogue is not always successful. However, the integration of different academic perspectives has yielded many substantive and innovative results. At its best, bioethics is now a discipline that has a rich arsenal of both well-established and innovative theories at its disposal that, if applied well and appropriately, can generate genuinely novel theoretical insights and inform practical solutions for complex ethical challenges.

Partly due to the contribution of a broader range of disciplines to bioethics, and partly in response to an increasing discontent within the discipline, bioethics has accommodated empirical research at an ever-growing rate over the last two decades. Many bioethicists as well as outside commentators – often those involved in practical decision making, such as clinicians or policy makers – have voiced dissatisfaction with the foundational approach of applied ethics as lacking a recognition of the facts and dilemmas of the 'real world.' In parallel, the growing influence of the evidence-based paradigm in medicine stimulated interest in empirical studies aimed to inform bioethical reasoning (Borry et al., 2005). Many clinical ethicists became engaged in empirical research due to their strong integration in medical settings. In addition, the aforementioned growing contributions from disciplines such as psychology, sociology, and political science have led to a stronger incorporation of qualitative and quantitative methodology into bioethics. Last but not least, some of the debates that emerged over the last two decades on issues such as the social determinants of health, brain mapping, and systematic reviews of reasons have been underpinned by discussions of empirical methodology and/or data, and have required in-depth knowledge of the empirical evidence.

Robust knowledge of the empirical evidence is now regarded as essential for the formulation of good normative arguments that are subsequently applied in practice, for example, on questions such as: What shapes the needs and desires of people who are dying? What values, goals, and risks do women and couples consider when deciding whether or not to donate their unused *in vitro* fertilization (IVF) embryos for research? Nevertheless, the relationship between empirical and normative perspectives in bioethics has not always been smooth (Hurst, 2010; Goldenberg, 2005). This is largely due to the difficulty of determining how empirical data could and should appropriately inform normative reasoning without violating the fact–value distinction, displacing sound normative argument, or producing trivial insights that could have easily been gained by other means. Empirical researchers, on the other hand, have complained that bioethics has incorporated empirical research without also fully taking on board the rigorous quality standards to which those designing empirical studies are held within their respective disciplines. There is no question that bioethics as a field has greatly benefitted from the inclusion of empirical data in its core debates. Examples of well-designed studies abound that inform normative thought in an appropriate and illuminating way. However, the discussions between the two perspectives on how to marry normative reasoning and empirical research are far from over.

Both described changes to bioethics' methodology can also be regarded as part of a trend toward a more professionalized discipline with rigorous research standards and tools for evaluating the quality and impact of resulting publications. By the end of the twentieth century, the first big push toward professionalization was more or less over, at least in the developed world, with research ethics committees, national ethics councils, large bioethics research projects, and devoted institutions and journals firmly in place in most Western countries, and increasingly in the developing world as well. This trend is continuing; the postgenomic era of bioethics also marks the time when bioethics has arrived in the scientific mainstream insofar as its output is now also judged, in most countries and university systems, by the same methods as other research – that is, the impact factors of the journals where they are published; how influential they have been in the clinical, societal, and policy-making domains; and so on. This has to do, in part, with changes in how academic research is

assessed in general, and also with the interrelation between science and bioethics, for example in the large ELSI (ethical, legal, and social implications) projects around the time of, and following, the HGP, as described below.

Emerging Subfields, Topics, and Debates

Beyond Gen-Ethics

From the beginning of the HGP, bioethics has played a particularly important role. When the HGP was set up, it was decided that a particular percentage of the public funding involved (3–5%) would need to be dedicated to the study of the ethical, legal, and social aspects/implications (ELSA, aka ELSI) of genomics. This, and subsequent similar obligations by, for example, the European Commission, have given rise to the establishment of a multi- and interdisciplinary yet distinct field studying such aspects. There can be no doubt that the large ELSA projects of the last two decades have contributed important findings and supported bioethics' higher visibility in scientific research and with the public. However, the ELSA develop-ment has also spurred considerable critique. ELSA researchers in genomics and postgenomics have been criticized for playing the 'handmaidens' of scientists by granting legitimacy to scientific advances (e.g., Zwart and Nelis, 2009). From another direction, ELSA research has been criticized for doing the opposite, namely, for overemphasizing potential pro-blems and thus hampering research that could potentially be lifesaving for people (e.g., Taylor, 2008). These controversies are bound to continue.

As mentioned in this article, bioethics in the postgenomic era is increasingly addressing challenges in areas of bioscience and biomedicine that integrate knowledge and practices from more than one discipline. For example, the field of personalized medicine aims to use data on people's biological and environmental (including social and lifestyle-related) characteristics in order to render the classification, understanding, treatment, and prevention of disease more precise (i.e., more 'personalized') (ESF, 2012). Its remit includes, at least potentially, every area of biomedical research and every medical specialty. Its success will rely on the participation of patients and citizens who, for example, collect and provide data for their own diagnosis and treatment, and often also release it for research use. The involvement of the commercial sector in the development and provision of personalized medicine is seen by some as a desirable goal, and by others as a necessary evil; everybody agrees, however, that commercial companies will play an important role here. Such strong integration of scientific and medical disciplines and specialties, with actors from public and private domains, presents bioethics with complex challenges, as decision making increasingly takes place in a decentralized and networked manner. Moreover, understanding and tracing the implications of decisions have become very difficult endeavors. The result is that bioethicists can say very little about issues in integrated fields such as personalized medicine *in abstract terms* (other than reiterating some concerns lying at the core of the discipline, such as justice, equity, and the prevention of harm). Unlike in most other areas of bioethical inquiry, bioethical scholarship in these integrated areas tends to address particular concrete practices (such as pharmacogenomics testing of a particular patient group in a specific institutional and national setting).

Other examples of growing domains of bioscientific and biomedical practice that integrate a multitude of different disciplines include epigenetics, which merges molecular biology expertise with the need to understand the influence of environmental factors on the genetic dimension, and synthetic biology. This latter field applies an engineering approach to building biological systems.

What these integrated fields have in common is that they are underpinned by large-scale databases and repositories. These databases and repositories – depending on the purpose for which they are used – comprise annotated biological and other kinds of data (epidemiological, lifestyle related, technical characterizations, etc.). Being seen by many scholars as key infrastructures of the life sciences in our times, their establishment and governance pose complex problems in their own right (Kaye et al., 2012). Core challenges include the need to balance the protection of privacy and confidentiality of personal data, on the one hand, and the quest for ever larger, better characterized databases that could yield new insights when adequately mined, on the other.

The question of when to inform people of incidental findings based on their genetic and genomic data is another hotly debated issue. Some scholars also critically question the considerable resources needed for the establishment and maintenance of large-scale databases that, if employed for other means, could lead to faster health outcomes and/or address the pressing health needs of larger parts of the world's population.

Neuroethics

An important newer subfield of bioethics that emerged in the postgenomic age focuses on the ethical, legal, and social dimensions of neuroscientific research. The increasing attention that bioethicists pay to neuroscience was triggered by the new possibilities and scenarios that emerge with the advance of new imaging techniques (particularly magnetic resonance imaging (MRI)). Neuroimaging is said to provide 'glimpses into the workings of the brain' through 'brain mapping.' New developments in neuroengineering, cognitive enhancement, neurosurgery, and so on have also been important drivers of bioethical interest in this field. The interface of neuroscience and bioethics is now known as 'neuroethics' and has attracted considerable funding in its own right (e.g., the National Core for Neuroethics, University of British Columbia, Canada, and the Oxford Center for Neuroethics, United Kingdom). Simultaneously, it has been called into question whether contemporary neuroscience poses any genuinely new bioethical challenges to warrant so much attention. Scholars who have put forward this argument hold that most of the ethical issues addressed within neuroethics are in fact *not* specific to applications of neuroscience and have been taken up previously, for example in relation to the ethics of genetics (Illes and Racine, 2005). Notwithstanding such questions, the usage of 'neuroethics' to describe a subdiscipline of bioethics is now firmly established, not least through the foundation of research institutions bearing it in their name as well as a journal of the same name (*Neuroethics*, published by

Springer). And regardless of where one stands on the question of whether neuroethics tackles any genuinely novel issues, one of the benefits of this young area in bioethics is that it showcases the integration of expertise emerging from interdisciplinary work that is initiated and led either by ethicists and social scientists, or by neuroscientists and policy makers. Many of the now-classic articles on ethical issues arising from developments in neuroscience have not been written by ethicists, but by neurologists, neuropsychologists, or neurosurgeons drawing on bioethical concepts and methodologies (e.g., Farah, 2002).

Neuroethics is often broadly divided into two categories – 'the ethics of neuroscience and the neuroscience of ethics' (Roskies, 2002) – with obvious overlap between the two. The latter examines the neural bases of moral reasoning, for example by trying to establish whether there are two different systems for moral judgments at work in human decision making, one 'utilitarian' and one 'deontological' (Greene et al., 2004). What are the neural bases of agency, responsibility, and free will, and could these concepts be illusions? Some scholars also subsume the examination of the neural correlates of decision making in general under the label 'neuroscience of ethics,' whether in economic or consumer choice settings, or in relation to love, religion, or sex. The former area – the ethics of neuroscience – addresses, among other things, the potential and actual consequences of interventions in the brain through a variety of methods, such as psychopharmacological drugs, psychosurgery, tissue engineering, and brain–computer interfaces. Discussions focus, for example, on questions such as whether it is ethically appropriate to use drugs to enhance cognition and mood beyond what is considered 'normal,' whether and what brain interventions that change personality are permissible, and what effects neuroscientific interventions and research have on society (Glannon, 2011).

Population-Level Bioethics, Public Health Ethics, and International Bioethics

Arguably the biggest newer development in bioethics is the inclusion of a population perspective. Much of traditional medical and bioethics focused on ethical issues to do with individuals and their rights and obligations – patients, doctors, transplant and stem cell donors, and so on – or with the relationship between individuals and society, present in discussions such as on the rationing of health care or the regulation of reproductive technology. As recently as 2007, however, the field and the profession could still be accused of ignoring the many ethical issues arising from a consideration of population-level data and problems (Brock and Wikler, 2007). This is currently changing; population-level bioethics is growing at high speed.

One of the most important initial drivers of this was an increased awareness of the population-level health data that epidemiology and other public health disciplines had been amassing over the last half-century. The analysis of these data has made it increasingly obvious that there are, for example, significant socially determined health inequalities along the whole socioeconomic gradient within countries, and even greater ones between the populations of different countries (e.g., Marmot, 2004). These findings, replicated multiple times and across the whole globe, have sparked an intense discussion around questions such as which socially determined health inequalities are unjust, and how these can be addressed or compensated for (Powers and Faden, 2006; Daniels, 2008). Many bioethical arguments in these discussions have borrowed from philosophical debates about distributive justice and egalitarianism, invigorating these in the process, as well as from the more technical discussions in public health about the role of the social determinants of health and well-being, thus constituting truly interdisciplinary and often innovative work with impact on national policy making and international institutions (e.g., the World Health Organization (WHO)).

Population-level bioethics has also brought some new impetus to the long-standing controversy around the behavioral bases of health. The contested questions of whether some health inequalities that are linked to behavior should be compensated for or whether they fall under the personal responsibility of those engaging in these behaviors to some degree mirror the older debate about whether rationing should take personal health behavior into account (Buyx and Prainsack, 2012; Prainsack and Buyx, 2011). Population-level data on the social determinants of health have challenged some of the old arguments in favor of a stronger recognition and expectation of personal responsibility. On the other hand, the necessity to positively influence both socially determined health behavior and other socially determined inequalities has become ever clearer. An interesting contribution to how such influence could be wielded on a policy level has been brought to the field from behavioral economics (Thaler and Sunstein, 2008), and a lot of recent work in population-level bioethics and public health ethics focuses on the permissibility and form of 'nudges' based on the idea of 'libertarian paternalism.'

In parallel with the stronger focus on population-level health data, an awareness of the international dimensions of bioethics has also grown. This was and is particularly the case, again, with health inequalities, as these are most starkly obvious between the developed world and poorer countries, raising the question of the richer world's obligations to address them. Other topics that international, population-level bioethics addresses are – to name just a few – the 'brain drain' of health professionals from poor to rich countries, research priorities in developing countries, and other ethical issues in international research (e.g., Eyal and Hurst, 2008).

To a large degree, population-level bioethics and another newer bioethics subfield – public health ethics – overlap thematically. In addition to those already mentioned in this article, they also focus on topics such as pandemic preparedness and vaccinations. Public health ethics addresses some additional issues that are more specific to the discipline, such as the ethical appropriateness of particular public health programs. There are also a number of topics that have recently risen to prominence in bioethics that tackle even wider, international, and interstate ethical concerns, such as the effects of climate change, the consequences of new approaches to bioenergy, or the ever-present yet worsening challenges of food crises (e.g., Buyx and Tait, 2011; Nuffield Council on Bioethics, 2011). Due to

their complexity and relevance, these latter issues can be expected to receive even more attention in years to come.

The Dual-Use Problem

An issue that receives increasing attention in bioethics in the postgenomic era is the problem of dual use. 'Dual use' means that science (and applications) developed for civil purposes can also be put to other (e.g., military or even terrorist) uses. This dilemma is by no means new; it has been a bone of contention within policy and public debates in connection with nuclear science, behavioral genetics, and recombinant DNA research, for example. Bioethicists, however, have only more recently turned toward discussing dual-use problems in the life sciences (e.g., Ehni, 2008). A 2008 paper in *Bioethics* identified five obligations that should be met by scientists working in areas affected by dual-use issues (Kuhlau et al., 2008): these include engaging in response activities, considering the negative implications of research, and not sharing information. Especially the latter obligation – not to share or publish sensitive information – has been at the heart of a controversy in connection with papers reporting on experiments with avian H5N1 influenza virus transmission in ferrets in 2012 (Herfst et al., 2012; Imai et al., 2012). When both manuscripts were reviewed, The US National Science Advisory Board for Biosecurity (NSABB) suggested that only the general conclusions, but not the methodological details, should be published to prevent anyone from replicating these experiments with bad intentions (some even suggested that the research itself should be halted). Eventually, both papers were published, in a modified form, and both advisory committees and scientists agreed that oversight of such research should be intensified (Yong, 2012).

Dual-use considerations have also been very prominent in the ethical debate about synthetic biology (see, e.g., Douglas and Savulescu, 2010).

Human Enhancement

Medicine has been used to improve or enhance 'normal' human function or features for a very long time. Doping in sports and cosmetic surgery are well-established examples of this. However, over the last two decades, developments in medical technology and increasing demands to be 'better than well' have sparked interest in what has been summarily termed 'enhancement.' Examples range from the use of growth hormone in children with a predicted small height absent of any pathology, to hormone treatment to delay signs of aging, to mood, cognitive, and personality enhancement afforded through the use of psychopharmacological drugs and brain stimulation (e.g., Parens, 1998).

While the evidence of 'net' enhancing properties of medical treatments is, to some degree, still contested, a lively discussion has developed around a number of theoretical and ethical issues. The distinctions between concepts such as treatment and enhancement, illness and health, normality and pathology, and naturalness and artifice have been greatly contested, while others have focused on the ethical permissibility – or, indeed, the moral obligation – of such enhancements, particularly in minors; their potential effects on equality, society, and our understanding of what makes us human; if and how the medical profession should respond to requests for enhancement; and what policy options are available to address these issues (e.g., Savulescu and Bostrom, 2009). The debate, very active in the early 2000s, has recently quieted down slightly but is, nonetheless, still relevant.

Vision for the Future

Without any claim to comprehensiveness, these are some of the more recent trends that have had considerable impact on the way postgenomic bioethics has developed. One feature that is apparent in all of them is the increasingly fruitful interdisciplinary integration that has taken place.

While these debates and subfields can be expected to grow still further, there are of course a number of issues that have been of long-standing interest to bioethics, such as ethical questions at the beginning of life and in end-of-life care, as well as other areas of clinical ethics; the stubborn ethical challenges around policies for transplantation and donation of organs, gametes, tissue, and so on; ethical issues in research; questions of fair rationing in modern health care systems; ethical provision of modern reproductive services; and appropriate regulation of genetically modified organisms and related research activity, to mention just some of the most contentious ones (for detailed discussions of these, see the cross-references below). Bioethics, benefitting from the changes and developments that have been laid out in this article, will continue to seek answers and solutions to these knotty problems.

Abstract

This article describes the relationship between philosophy and bioethics. It begins by defining bioethics. It then explains how philosophy became the central academic discipline within bioethics, and discusses the relationship between philosophy and other disciplines in bioethics. The article then discusses the main contributing theories within philosophical bioethics, and concludes by briefly discussing the developing range of topics within bioethics.

Definition

The definition of bioethics is somewhat controversial. Different definitions are proposed, which focus on different accounts of its scope and of the methods used in its arguments and inquiries. However, for most practical purposes, a broad and inclusive definition is appropriate. We may define bioethics as the "field of normative problems and issues arising from biomedicine and medical sciences and their applications." This very broad definition is intentionally silent on the question of whether bioethics is a discipline, or even an emerging profession, and on the question of whether bioethics includes a concern with animal welfare, environmental ethics, climate change, or issues of law and social policy which have an impact on health without being directly related to the practice of medicine. Some writers in the field of bioethics would see gun control or sexual violence as being public health issues, and therefore claim that the ethical questions associated with these issues, and with interventions addressed to these issues, as falling within bioethics.

Philosophical bioethics is much more easily defined. It is the application of the methods, concepts, and theories of philosophy to the problems of bioethics. There are two ways of looking at this: one is to see philosophical bioethics as one part of bioethics, and not by any means the whole of bioethics. The other is to see philosophical bioethics as one part of a more general enterprise of 'applied philosophy.' Not all of applied philosophy is concerned with bioethics: indeed, not all of applied philosophy is concerned with ethics (or its sibling, normative political philosophy).

Philosophy and Bioethics

The relationship of philosophy to bioethics is complex. Philosophers have often written about issues that might now be considered characteristically 'bioethical' in nature: suicide is a clear instance of a topic of central interest to bioethics, which has been at the heart of philosophical thought and debate. Nevertheless, it would be absurd to argue that Plato or Hume were 'doing bioethics' when they wrote about the rationality or ethics of suicide. The description was unavailable to them; their conception of what they were doing and their reasons for doing it were quite different from the conceptions of modern 'bioethicists'; their intellectual, cultural, and religious environments were quite different and so on. If we consult the standard 'internalist' histories of bioethics, we often find the following historical train of thought. Classical philosophy from Socrates up to the nineteenth-century moral philosophers (including Friedrich Nietzsche, Auguste Comte, and Henry Sidgwick) was essentially concerned with how to live well. Problems of ethics were therefore central to philosophy. Once philosophy came to be dominated by logic, epistemology, and the philosophy of language (from Gottlob Frege and Edmund Husserl onward), ethics was displaced from its central role within philosophy. To a greater or lesser extent, not only did ethics stop being a prestigious 'research program' (to borrow Imre Lakatos's term from the philosophy of science) but also it started to become an object of outright skepticism within philosophy. By the mid-twentieth century the dominant paradigms for moral philosophy were the existentialist school, which emphasized authenticity and commitment to a project but eschewed any concrete moral judgments, and the post-positivist 'emotivist' school, which argued that the language of ethics had no objective content and was merely rhetorical in nature. There remained an active research program in moral *theology*, especially within the Roman Catholic Church, but philosophy, newly professionalized in the early twentieth century, took great pains to distinguish itself from theology.

Although, as we shall see, philosophy began to take ethics very much more seriously again from the 1960s onward, it remains true of most professional philosophers, and most philosophy departments as institutions, that although some parts of ethics – mainly those concerned with theoretical problems of mind and language – are 'proper' philosophy, most of what nonphilosophers think of as ethics is 'merely' … something; that something might be 'applications,' 'journalism,' 'critical thinking,' or 'public engagement.' To the extent that ethics (be it labeled bioethics, applied ethics, or practical ethics) is taken seriously, it is as a source of test cases. For instance, there is a growing literature on the ethics of human-induced climate change, and a good deal of this literature is concerned with fixing technical problems in the theory of utilitarianism, or with addressing the question 'why should I be moral,' with policy or practical recommendations coming into focus almost as a secondary consideration. This is not necessarily a criticism of philosophy or philosophers: it is a description of the nature of academic professional philosophy at this

point in its disciplinary history. Moreover, it can hardly be a criticism of philosophy to note that philosophers tend to work on problems that they recognize as distinctively philosophical, and to use the methods and paradigms with which they are most familiar and skilled. That said, an influential paper in the 1970s surveyed the field of philosophical *medical* ethics and concluded that medicine had 'saved the life of ethics' (and, he might have said, philosophy itself, Toulmin, 1982). It did this by throwing up a whole series of problems which were – to a philosopher – recognizably philosophical and intellectually challenging, and which forced moral philosophers to think more deeply both about these problems and about the moral theories they were using.

Some philosopher bioethicists have mistakenly taken this to be the whole story of bioethics. This is especially evident when one looks at the literature from the late 1980s onward arguing that the social sciences should play a greater role in bioethics. Philosophers critical of this position often argued as if philosophy was what was distinctive of bioethics, as if it were philosophy, which had saved the life of medicine. In part this reflects the then current perception that philosophy (at least in its Anglo-American versions) was mainly concerned with language and the clarification of concepts, so that the contributions of the social sciences would at most be of 'data,' which would be of rather limited use or relevance in analytical argument (a useful critique can be found in Hedgecoe, 2004.)

It is certainly true that philosophy made, and makes, a great contribution to bioethics. We will see this later in this article. But the attempt to claim bioethics for philosophy is quixotic. Historians and sociologists of bioethics as a social movement and as an intellectual enterprise have consistently shown that the philosophers were relatively late entrants to the field: the emerging field of bioethics was shaped to a far greater extent by theologians, lawyers, and scientists and medical professionals. Nevertheless it is true that philosophers came to play a major part in the shaping of bioethics, and its questions, methods, intellectual standards, quasi-professional entry criteria, and so on continue to be dominated by philosophy. One exception to this general rule is where bioethics has been taken up as a 'clinical' specialty (clinical bioethics), where the influence of the methods and norms of academic medicine is much more pronounced.

Philosophy and Social Problems in Bioethics: Introducing Principles

One way to account for the dominance of philosophy within bioethics is to point to the superficially obvious fact that in as much as bioethics is about moral problems, philosophy is the intellectual discipline that focuses centrally on morality and its structure. The difficulty with sustaining this line of thought is that other disciplines also lay claim to this territory. If we frame 'moral problems' slightly differently, as social problems, then it would appear that sociology and social policy might be the dominant disciplines (particularly given the concentration of mid-twentieth-century US sociology on 'social problems'). Equally, we might turn to history (in Germany, the history of medicine occupied a much more central role in thinking about 'bioethics' than did philosophy), theology, or law. Indeed, bioethics has periodically drawn on all these sources. A better explanation of the domination of philosophy in bioethics is needed.

Sociologist John H. Evans has argued that the role of philosophy in bioethics became central because the issues at the heart of bioethics were initially posed using language and concepts that were 'thick.' Thick concepts are concepts that combine description and evaluation. A good commonplace example is the concept of rudeness: if I say someone is rude I am both stating a fact which I believe to be true, and evaluating their conduct and character, and I am inviting you to agree with both the evaluation and the judgment of fact. Moreover, you cannot have the moral judgment without the factual judgment, or vice versa. The difficulty in complex societies is that thick concepts rest on background assumptions about social norms and values that may not be universally understood or shared. Evans argues that theological bioethics depends on a strong way on thick concepts (not only doctrinal requirements about articles of faith or religious observance, but also on thick conceptions of 'the nature and value of humanity' or 'human dignity'), in ways which make theological arguments very vulnerable to challenge in pluralistic societies. In its place, he argues, bioethics came to require methods of argument that did not strongly depend on thick concepts, and developed methods of consensus formation. Moreover, the social force of such consensus had to depend, or be seen to depend, on the authority of something other than custom, practice, doctrine, or tradition (which could be identified as the values of some specific social subgroup), but rather on a style of reasoning and a set of concepts that could be identified as common across cultural boundaries. Philosophy was seen to offer these tools. In particular, the emphasis in philosophy of scrutinizing the form and presuppositions of argument could be seen as immunized against the inbuilt moral judgments of 'common sense' – those very 'thick concepts' that were taken to be the problem in the first place (Evans, 2012).

It should be noted that this vision of philosophy as the means to overcome value conflict in pluralist societies involves a very specific kind of philosophy. In the second part of this article we will review the main philosophical methodologies applied in philosophical bioethics, but here we need to make the acquaintance of the most well known: the method of principles. This is most closely associated with the philosopher Thomas Beauchamp and theologian James Childress. Beauchamp was a staff philosopher supporting the preparation of the 'Belmont Report,' the report of the (US) National Commission on Protection of Subjects of Biomedical and Behavioral Research (published in National Commission (1978)). The National Commission had been established to report to the US President on the protection of research subjects in the aftermath of the revelations of long-term exploitation of African-American men who were participants in the 'Tuskegee Syphilis Study' from the early 1930s until 1972. The intellectual method of the Commission was to identify basic principles that underpinned the ethics of human subjects research, which could both account for the various concrete rules found in law and policy, guide formulation of new rules to cover situations currently not provided for, and assist in resolving differences in moral judgment. During the preparation of the Commission report, Childress joined Beauchamp in writing what became

Principles of Biomedical Ethics (first published in 1978, now on its seventh edition, 2013). While the Belmont report identified three principles (respect for persons, beneficence, and justice), Beauchamp and Childress identify four (respect of autonomy, beneficence, nonmaleficence, and justice) together with a process of 'specification' that ties principles to the context of application.

A key feature of the 'principlist' methodology is that it is not, and never was intended to be, a *sui generis* comprehensive moral theory. Rather, it begins from 'common morality,' the ordinary, everyday moral maxims that are taken to be more or less universal in social life, around which there is a rough consensus. The role of principles is to provide an organizing structure, or 'mid-range moral theory' (akin to sociologist Robert K. Merton's account of a 'mid-range sociological theory'), which both explains and justifies the lower level common moral doctrines, and enables these to be tested, broadened, and applied in novel or controversial contexts. The roots of this approach are various, drawing on moral philosopher W.D. Ross's theory of duties as prima facie principles, John Rawls's theory of 'reflective equilibrium,' American philosophical pragmatism, among others. But the crucial feature of this approach to thinking about bioethics is its emphasis on consensus formation as a method of overcoming moral conflict. In this regard, it is quite different from both piecemeal moral theories that argue from cases (in much the way common law reasoning works in Common Law legal systems), and critical moral theories that seek rational reconstructions of morality which overcome what proponents see as defects in common morality.

The 'principlist' approach in bioethics continues to be paradigmatic, and it is certainly the most widely taught method in bioethics. In part, this is because it is easily summarized, and can be taught without needing much – if any – prior background in philosophy. As such it is particularly appealing in medical and health care education and training, where bioethics is taught as a 'clinical skill,' often over the course of just a handful of classes, and often where the assessment may be in the form of automatically-marked multiple choice questions (or similar). The form in which the principlist approach is taught, however, neglects all the subtleties of Beauchamp and Childress's own writing, and all the patient attention to common morality and its detail. Instead, the focus tends to be on the Four Principles themselves, treated as a list and without much attention to how they interrelate. The crudest versions emphasize 'respect for autonomy' to such an extent that the other three principles are either neglected altogether or treated as mere restatements of the autonomy principle. Critics of bioethics commonly note that justice almost always seems to disappear from discussion, or is treated in narrow terms as concerning economic distributive justice. One way out of this set of criticisms is to restate the basic ideas of Beauchamp and Childress with new, alternative principles. This is often done where the original principles are taken to be 'American' or 'Anglo-Saxon' in nature. Versions of 'European' principles have been stated, for instance, where it is unclear whether they are meant to be better principles, or simply local principles. The universalism of principlist theory is something its proponents do insist on, yet it is at least arguable that both in terms of its basis in common morality and in its application to specific contexts it remains much more 'culture-bound' than it would at first appear. Equally, the criticism that it is falsely universalist, and insufficiently focused on culture, structure, power, and agency is also leveled at principlist bioethics (for discussion, see Macklin, 1999). The problem here is that these criticisms can be leveled at any philosophical theory, and indeed at philosophy itself, and the best answer to these criticisms must be philosophy's own reflexive self-awareness and self-criticism of its presuppositions and conditions of possibility.

Philosophical Methods in Bioethics

We introduced principlism to explain how philosophy came to take up a central role in bioethics as a method for resolving value conflicts in public discussion and policy making. Another feature of principlism is the way it generated an efficient method for generating policy in bioethics. An important feature here is the nature of philosophical expertise. At least in the early years of philosophical bioethics, the expertise of philosophy was seen as on the one hand its lack of doctrinal presuppositions (in contrast with law or theology) and on the other its methodological rigor (in terms of commitments to analytical clarity and logical consistency). As with other emergent disciplines, bioethics came to have its own doctrines, canons of literature, methodological rules, and so on. A good example here is the way bioethics took up the doctrine of consent from law, but has developed that doctrine in ways that now mean that when bioethicists and lawyers speak to one another about consent they often do not understand one another. Yet the overall image of philosophy as providing the 'view from nowhere' (in Thomas Nagel's memorable phrase), dispassionate, analytic, and logical persists. From the point of view of intellectual history, however, this image links philosophy in bioethics to a very specific time and place, namely to mid-century Anglo-Saxon analytical philosophy (Nagel, 1986). This remains the dominant tradition within philosophical bioethics, although, as we will see, there are other important traditions which are of growing importance.

Conceptual analysis plays an important role within philosophical bioethics in its own right. The idea is that before we can carry out normative reasoning, we must be clear about the meaning and scope of the terms under discussion. A central example in discussions of end-of-life care, for example, is that we must understand correctly what 'killing' means. Are withdrawing life support, failing to offer life-sustaining treatment in the first place, and administering a poison all correctly identified as 'killing'? We can, presumably, get clear on this question without taking up a position on whether killing is ever morally permitted or even required. Related to this, can we clearly distinguish an act from an omission? Philosophers often proceed on the basis that we have ways of identifying the meaning of linguistic terms in terms of concepts, and ways of clarifying our understanding of concepts, which are normative for their proper use, and contrast with the ways words are actually used by individuals or groups (for instance, by lawyers in a legal system). Not all philosophers think this is a sensible or even intelligible way of proceeding – for example, Ludwig Wittgenstein, who argues that we should look for meaning in use, or Gilles Deleuze, who argues that philosophy is about

creating, not finding, concepts. Nevertheless, the analytic move is often a useful one in trying to set out what the nature of the debate is, even just as the first, and not the last, word.

Normative moral philosophy is the branch of philosophy which considers theories of right action. It is related to *metaethics*, which considers the metaphysical and epistemological basis of rightness and the good. In metaethics, we are concerned with the questions "Why should I be moral?" and "Is anything objectively good?" Bioethics rarely engages directly with metaethics, although bioethics and bioethicists rarely subscribe to radical skepticism in metaethics (versions of which include egoism, subjectivism, and relativism). Occasionally, metaethical issues do become salient to bioethics, sometimes in connection with the status of bioethics itself (see the discussion of the universality or otherwise of principles, above), sometimes more concretely in discussions about the nature of 'quality of life' or the value of beginning or ending a human life. Here, for reasons of space, we concentrate on normative ethics.

The main doctrines in normative ethics are *utilitarianism*, *Kantianism*, *communitarianism*, *virtue ethics*, and *casuistry*. Each of these theories has a distinctive history within moral philosophy that predates the appearance of bioethics and continues to evolve alongside and sometimes in dialogue with it. Before we see brief descriptions of each, we need to consider the nature of theory in normative ethics and its implications for bioethics in practice. The relationship between bioethics and normative ethics runs two ways. From normative ethics to bioethics, a writer who is a defender of a particular theory in normative ethics may well draw a conclusion relating to a topic in bioethics, and propose it as the right thing to do. And from bioethics to normative ethics, a writer who thinks that the proffered conclusion is obviously wrong, wicked or absurd, will argue that this shows a flaw in the normative theory in question. In principle, such disputes can be resolved by seeking to optimize coherence between moral intuitions, robustly supported conclusions in analogous cases, evidence about people's moral beliefs, and logical consistency in theoretical construction to come to a conclusion about where the (moral) truth lies. In practice, these debates rarely run so smoothly or conclude within any finite time horizon. This is one reason why debates come down so quickly to debates about personal autonomy: it is often argued that where consensus on a moral matter cannot be arrived it, then it will be oppressive to impose a moral view on someone who does not hold it, unless to prevent avoidable harm to nonconsenting or vulnerable others. However, even this strategy is not beyond criticism, linked closely as it is to the political doctrine of (Millian) liberalism, in itself frequently criticized. Another way in which theory and bioethics come together is rather different. One way in which a bioethical proposal can be tested is to see whether it can be demonstrated as holding true even when we start with different theoretical starting points. Thus, if Kantians, utilitarians, and communitarians all reach the same conclusion, then we have some confidence in saying that the proposition is true *independently* of the theoretical route we took to get there. (Obviously, the argument is more complicated than that, but this is the idea). The difficulty here is in avoiding 'begging the question' (i.e., implicitly or explicitly assuming what we are setting out to prove).

Utilitarianism is arguably the most influential normative theory in bioethics other than principlism. It is the best known version of 'consequentialism,' which is the theory that actions are to be judged good or bad with reference only to the goodness or badness of their consequences. There are various reasons for this. One is that it is easily stated: act so that the action you perform promotes the most good, compared with all the other actions you could perform in the circumstances. Another is that utilitarianism has a natural representation in classical economics, so that in problems involving the allocation of resources, the utilitarian answer and the economists' answer will be strikingly similar. A third is that utilitarianism often produces strikingly interesting, not to say controversial, answers. Outside the principlist mainstream, the most influential work in bioethics was that done in the 1970s by Australian philosopher Peter Singer, a well-known utilitarian, whose papers on animal welfare, euthanasia, and the permissibility of infanticide of severely disabled newborns were both remarkably clear and troubling to the 'common morality' of the majority. Utilitarianism is the best example of a 'critical moral theory,' which uses clearly stated premises and logical argument to challenge widespread assumptions – both by positive advocacy of alternative views and by critique of the coherence of the mainstream assumptions. Utilitarianism has been criticized within and beyond philosophy on a number of grounds. The first is the way it generates unpalatable conclusions; utilitarians often respond by saying that it is insufficient to say that you dislike their conclusions, you must argue why they are wrong, and they propose a critique of the role of 'intuitions' in moral argument to overcome objections. Unfortunately in most moral arguments, in the end, intuitions are all we have. Another problem in utilitarianism is specifying the nature of the good we are to promote and how we are to measure and aggregate it. While the philosophical literature is very rich in discussions of these issues, this can make practical applications hard to justify. To take an example, in an area where utilitarianism is naturally strong (distribution of resources), it is often argued that distribution should take account not only of economic efficiency but also of equity (a variety of fairness). Utilitarians, in theory, can deal with this by allowing for how much equity matters to individuals (or, how unhappy does an unfair distribution make us) to offset against the welfare or pleasure conferred by the distribution independent of equity considerations. But in practice this is very difficult to do. Hence, the apparent clarity of utilitarianism (an easy principle that can be applied simply) seems to melt away, and undermine its value as a decision tool that guides action.

Kantianism is a shorthand for a variety of duty-based theories of ethics, which contrast with consequentialist theories. The most well known is the theory of ethics developed by Immanuel Kant in the late eighteenth century. The details of how duties are identified and justified are somewhat technical; in practice, the interesting question is not so much how we identify duties – principlism gives one answer and may be considered a Kantian theory – as how we reconcile conflicts or uncertainties governing their application. One form in which duty-based theories of ethics are relevant in bioethics is in the form of codes of medical ethics, which specify lists of obligations and prohibitions and which are intended to be followed by professionals. In one sense this is outside philosophy, in that they have a quasi-legal status, but in debates about their reform and extension philosophical argument can come into

prominence. A good example is the Declaration of Helsinki that governs the ethics of research in medical research as its major international statement. This has been revised several times in recent years, always with attendant controversy, largely because of its attempt to grapple with specifying the duties researchers have to research subjects and to communities where they carry out research, specifically in avoiding unethical exploitation. Unlike utilitarianism, such duty-based theories as are applied to this kind of problem lack clear decision rules that account for solutions.

Virtue ethics has its roots in ancient philosophy (notably Aristotle and St Thomas Aquinas), but in its modern forms responds both to the challenges of consequentialist and duty-based theories noted above and to the importance common morality places on motivation and intention in ethics. By focusing on the moral character of the agent, rather than on his or her actions, it is hoped that we can describe the kind of personal characteristics that make for right action. Virtue ethics is often linked to *communitarianism* that focuses on the characteristics of good societies (rather than good personalities) but shares a common focus on traits, rather than actions, and dispositions to behave in certain ways. It is also notable that traits found praiseworthy in virtue ethics (such as courage, integrity, and honesty) are examples of the 'thick concepts' we mentioned above, and which depend on a social context for both their definition and for the criteria by which they are judged. Both virtue ethics and communitarianism are strongly critical of the 'rationalism' they perceive in both duty-based ethics and utilitarianism, and are often (although not always) associated with forms of political conservatism. Critics of virtue ethics and of communitarianism focus on this perceived conservatism, as also on their lack of focus on actions and rules, which they allege make for relativism and uncertainty.

Casuistry identifies the weakness of all the above theories as lying in their attempts to be excessively abstract and insensitive to the specifics of situations. Casuistry focuses on the moral issues in specific cases, and seeks to resolve them by carefully identifying the cases that are relevantly similar, inferring a rule that covers all these cases (but not the cases which are in relevant respects different) and deducing from that rule what is morally required in the case at hand. To some extent all moral reasoning involves an element of casuistry (in defining and describing the situation of moral agency well enough to allow the moral problem to be identified), but casuistry avoids theoretical argument, instead proceeding in a quasi-inductive manner. Casuistry has a connection to virtue ethics and communitarianism in the form of narrative ethics, which seeks to analyze moral problems in the form of story structures that seek to build coherent narratives, which 'make sense' of the situation. Virtues map onto character traits that make sense of the characters in the story as seeking to tell coherent stories about themselves, which are consistent with our concepts of good lives (and good stories).

Other Traditions in Philosophical Bioethics

Bioethics has become thoroughly internationalized in the past 30 years, and while one of the factors that has enabled it to travel is the dominance of the English language (and hence, up to a point, English-language ways of doing things like philosophy), the influence of other philosophical traditions is increasingly important. Traditions in European philosophy (notably phenomenology and hermeneutics), focusing on meaning and experience, rather than conceptual analysis and normative moral theory, have been particularly influential in work in ethics in mental health and – especially – in work that seeks to elaborate the nuances of complex relationships of care. Unsurprisingly, perhaps, this approach in philosophy is closer in spirit to certain kinds of qualitative social inquiry, and is one area where philosophical bioethics works most closely with the social sciences. This kind of philosophical engagement with health and illness is sometimes considered to be external to bioethics, in part because of its caution about making explicit moral judgments and emphasis on understanding, and in Europe there is a strong tradition of 'philosophy of medicine and health care,' which draws on hermeneutics and philosophy of science as much as on moral theory.

Another complementary field to philosophical bioethics is theological bioethics; philosophy tends to resist strong engagement with theology in this domain, in part because of its social history as a discipline that seeks to avoid close identification with any particular moral, social, or political group in the name of wide social consensus, in part because of a strong tradition of secularism in bioethics, and in part because of the politics of bioethics.

Because of the social controversies that give rise to many prominent issues in bioethics (embryo research, *in vitro* fertilization, euthanasia, and human enhancement, to name but a few examples), social authority to speak on these topics is often contested. Bioethics is faced with a paradox of seeking to be 'beyond politics' and at the same time central to an intensely political field. Religious affiliation is just one dimension of this: to one party 'Catholic bioethics' may simply be 'bioethics, done rightly'; to another it may be 'not bioethics at all, but merely the doctrine of some group I don't care for.' To some extent this is overheated: utilitarian bioethics is a respected subfield, and individuals who work on it can move, often seamlessly, between contexts in which this is what they are publishing on to situations where they are expected to be more 'ecumenical' and back. The same can apply to Catholic, or Marxist, or feminist bioethics. On the other hand, it is not so simple as saying "there is no such thing as hyphenated bioethics, only good bioethics and bad bioethics." The flourishing field of feminist bioethics starts from an explicit premise that is both ethical (women are equal in dignity and importance and value to men) and political (in order to overcome patriarchal oppression of women and the silencing of women in public and private discourse, we should privilege women's voices and women's issues in bioethics as a strategic matter). It is not a question of leaving one's politics (or faith, or conscience) at the door.

The role of politics in bioethics has become more important not only because of its social context, but also as a focus for bioethical research. One illustration of this is the rise to prominence in recent years of 'public health ethics,' which focuses on health policy, resource allocation, population health, and – increasingly – global justice. In this focus it is inevitably engaged with questions of social structure, power, and collective choice, and as such it has increasingly

acknowledged the importance of normative political philosophy alongside normative moral philosophy.

Conclusion: The Topics of Bioethics

There is not space here to examine any bioethical topics in detail. Bioethicists work on such a wide range of topics within health, medicine, and biomedical research that it is impossible to do that breadth justice. However, in broad terms we can distinguish the following subfields of bioethics: clinical bioethics, which focuses on the ethics of clinical practice in medical and nursing care of patients (usually in hospital settings, but not always); public health ethics (with a major emphasis on the ethics of preventive medicine, health promotion, infectious disease control, and resource allocation in health systems); so-called 'regulatory bioethics' (which focuses on the normative principles that govern the regulation and supervision of specific technologies in medicine, including genetic technologies, applications of neuroscience, and assisted conception, and also on the normative underpinnings of health law as applied to abortion and euthanasia). One thing that all these fields have in common, it may be argued, is that there is a more or less prevalent tendency to treat these topics ahistorically and with limited attention to social context. Bioethics is commonly criticized for a kind of socio-technical determinism, particularly when engaged in prospective regulation: if we permit cloning, then this will happen … In a sense this is the 'original sin' of bioethics. If we ask philosophers to think about the moral implications of technology, then it is unsurprising if they do exactly that, rather than challenging the assumption that it is the technology, which will make the difference. On the other hand, there are encouraging signs that the development of bioethics, in closer contact with the social sciences and wider humanities, will continue to enrich debate and – with due humility and reflexivity – enhance it.

Abstract

Within sociology, biographical research has expanded during the last 20 years. The common ground is still the interest in understanding the interrelation between societal developments (including those on a global scale) and the experiential world of people. How experiences are organized in specific social contexts in the perspective of a lifetime and its generational relations to get oriented in everyday life and in the world, is the core topic in biographical research. This article gives an insight into recent methodological developments in biographical research and its variety of contributions to major issues of globalizing societies, such as history and memory; collective identities; migration and transnational biographies; gender and intersectionality; and the search for new concepts of inclusion.

Since the last article on 'Biography and Society' to this encyclopedia written by Daniel Bertaux (Bertaux, 2001), the founder of the ISA Research Committee 38 on Biography and Society, much has changed in the field of sociologically oriented biographical research. In his article Bertaux pointed at the obstacles that sociological–biographical research had to face in its long history, which started in the 1920s with the major investigation by Thomas and Znaniecki on *The Polish Peasant in Europe and America* (Thomas and Znaniecki, 1918–1920/1923) and the famous studies from the Chicago School (see references in Bertaux, 2001). After flourishing in the 1930s and 1940s in the US and a little longer in Poland, research based on biographical material subsequently was pushed to the background of mainstream sociology. It was only in the 1980s that it was revived again, still against considerable criticism and skepticism. In contrast to the period in which this approach was marginal, it has undergone dynamic development during the last 20 years. The most remarkable development is that biographical research has turned into a success story. It has continued to be broadly institutionalized, and nowadays there is more biography in sociology than ever before. This shows, for example, in the emphasis on situated knowledge brought into theoretical discussion. The early dictum of Martin Kohli to talk about ourselves because we as scholars are biographically shaped, has become an indispensable part of the teaching of classical sociological theory, through the introduction of the biographies of respected classical theorists. Furthermore, a constantly growing body of scholarly literature on a huge variety of topics investigated through biographical perspectives and methodological approaches, appears worldwide in many different languages (ISA RC 38 Newsletters, 2008–2013). These wide-ranging theoretical and methodological approaches were presented in extended compilations (Miller, 2005; Harrison, 2009). Last but not least, there is a growing area of research by PhD students and senior scholars that succeeds, though still rarely, in obtaining funding on a large scale, be it by the EU (Apitzsch and Kontos, 2008; Chamberlayne et al., 2002; Miller and Day, 2012), or by national funding institutions (Rosenthal et al., 2013).

Even though the field is growing and diversifying internationally so that it is almost impossible to cover it in one short article, there is still common ground. The core question (originally put up by Thomas and Znaniecki), which focuses on how changes in society are connected with varying organizations of the self and the processes of reorganizing family, work life, and generational relations as well as institutional settings, is still the basic orientation of biographical research. In short, one of the main purposes of biographical research still is to understand how processes of personal and societal change are intertwined and inseparable. The assumption is that 'making sense' and orienting our actions in the modern era increasingly requires reference to the construction of biographies and institutionalized life courses. People are more and more organizing their experiences and general patterns of orientation in biographical frameworks; other institutional contexts based on strong normative patterns such as 'family,' 'nation,' 'class' and their interrelation, have been changing more or less profoundly (Fischer-Rosenthal, 2000; Kohli, 2007). The social concept of 'biography' therefore is regarded as a relevant field of interference between institutionalized societal reality and the experiential world of individuals in modern societies. It is assumed that the construction of biographies is a social practice in which the societal and the personal are closely interrelated. These processes of making sense are especially intense in periods of radical social change, when institutionalized ways of interpreting and orienting in social situations and the world are called into question and new organizations must be built. In general, 'biography' is regarded as a field in which social processes of continuation and transformation constantly take place. To explore the implicit as well as explicit practices of 'doing biography' in different social fields is the general purpose of analysis, in order to understand society from within, which also means understanding it from the perspective of the actors.

To illustrate the specific contribution of a biographical perspective for understanding actual developments in present societies and also with regard to their historical backdrop, some research areas are presented in more detail. Their selective choice is based on the topics, which were and still are, prominently discussed in the context of the ISA Research Committee

38 on Biography and Society. First, developments in methodology and methods are briefly outlined. Secondly, some insights in scholarly contributions to the research on major topics of globalizing societies are provided, e.g., from the area of biographical research on history, memory, and politics; on collective identities; on migration and transnational biographies; on gender and intersectionality; and on social inclusion.

Developments in Methodology and Methods

There is not just a single biographical approach, but a variety focusing on different aspects, e.g., on the life course (Kohli, 2007); biographical trajectories (Schütze and Riemann, 1990); turning points (Hackstaff et al., 2012); relations between the lived life and the life story (Rosenthal, 1993); gendered biographies (Davis and Lutz, 2002); generational transmission (Inowlocki, 1993; Rosenthal, 2010); specific strands of experience like the work life (Brose, 1989); health careers (Bell, 2009; Frank, 2002; Ettorre, 2010); or different life phases like childhood, adolescence, and older age (see citations in Kohli, 2007). Likewise, theoretical concepts as well as methodological and methodical paths to access the complex evolvement of experience and action patterns in specific local and global contexts have diversified. One strand, which is related to phenomenology, the sociology of knowledge, and partly also to critical theory, is mainly based in narration theory (Bruner, 1987; Kohler Riessman, 2008; Rosenthal, 1993; Schütze, 2008; Frank, 2010) focusing on how a story is told and what this can reveal about patterns of action and experience and their structural meaning in a biography. The narrative form itself is regarded as a means to organize experiences in a temporal and thematic order that makes sense of what we have lived through, and which explicitly as well as implicitly, guide our actions. Biographies in this perspective are not understood as mirrors or copies of lived lives but as narrations produced in a current situation, relating to past experiences, the present situation, and also future expectations in communication with others. The experiences and processes, along which orientations and patterns of action develop and change in relation to specific social contexts, are reconstructed mainly by means of in-depth and comparative analyses of individual cases. Another strand, based more in materialist and structural theories, relies not so much on single-case analyses of biographical narrations, but on a broader ethnographic approach aiming at reconstructing the contexts in which narratives take shape. Recurrent participant observation over a longer period of time, the integration of a variety of empirical material aimed at creating an overall picture of a specific social context, are here the methods of choice. Last not least, scholars in this area also follow theoretical assumptions and criticism of discourse analysis, questioning the concepts of the 'individual,' the 'personal,' or 'subjectivity' in general, which in part was sometimes naively emphasized in biographical research, but not throughout theoretical discussions (Stanley and Temple, 2008).

Given lively discussion between different schools of biographical research, further advancement of methodologies and methods is vital. Narrative approaches are combined with ethnographic research (Delcroix and Pape, 2010) as well as with discourse analysis (Völter et al., 2005), and new approaches are created by linking to developments in other research areas. One of the most intriguing lines is to take the corporal and emotional experiences in processes constituting social life seriously (Plummer, 2001) also taking in feminist theory, which has pointed at this dimension already for some time (Davis, 2007). The study of the biographical significance of the body and especially passion (aspects which are not easy to grasp from the sociological point of view) is new ground for methodological and theoretical reflection (Davis, 2014b). The incorporation of visual sociology into biographical research (Bell, 2010; Breckner, 2013; Dussel and Gutiérrez, 2006) also provides new impulses. The importance of the visual dimension in actual interaction (which increasingly is organized via the social media) and the creation of (new) images of ourselves and of families, generations, and milieus has just started to be explored from a genuine biographical perspective. Its potential contribution to the rapidly growing field of research on the use of globalizing media and its impact on social life is to provide case-based, in-depth analysis on the biographical significance of visual self-presentation intertwined with oral and written communication. Theoretically promising are explorations how patterns of a 'narrated self' interact with patterns of a 'showing self,' and whether the increasing dominance of the visual dimension in everyday life in general is changing biographical concepts.

Globalizing Societies from a Biographical Perspective

Apart from promising developments in methodology and methods, which always have been and still are, closely connected to the field of qualitative and interpretive methodology, scholars are dealing with topics highly relevant in globalizing societies. In a brief overview the author mentions just a few to give an impression of what has been extensively investigated and published during the last 15 years, with focus on the major fields of migration and transnational biographies.

History, Memory, and Politics

Together with oral History, biographical research became prominent mainly in the 1990s and 2000s in revealing how World War II, and especially the Holocaust, affected and shaped the lives of millions of people, making them perpetrators or victims, or both (Inowlocki, 2000; Kazmierska, 2012; Rosenthal, 2010). The aftermath of the still not wholly graspable atrocities became accessible to subsequent generations through the life narratives of previous generations and examination of the processes of generational transmission. In this line, the creation of memory and, more generally, the reshaping of the past from a present perspective in conjunction with the complexity of lived lives, collective narratives, and discourses are points of interest. The knowledge gathered in this research area, revealing the close interrelation of biographical processes, collective trajectories, and major historical upheaval (Schütze, 1992), became fundamental. It expanded through the researching of the crash of the Soviet system and the consequent restructuring

of East European societies after 1989 (Humphrey et al., 2003; Breckner et al., 2000; Bertaux et al., 2004; Semenova, 2002; Andrews, 2007), as well as the end of the Apartheid regime and its aftermath in South Africa (Coetzee, 2011; Stanley, 2006; Coetzee et al., 2004). Against this backdrop the experiential background of political trajectories and actions has become a more broadly discussed topic in recent biographical research. In the German context, for example, the situation of two societies, the GDR and FRG, fusing into one after 1989 with major transformation processes in institutions (mainly in the disappearing GDR), political trajectories, and social movements has called for systematic biographical research. Likewise, the considerably growing right wing activities of women in East and West Germany during the last few years raised questions concerning the biographical background and impact of extremist political orientations (see exemplary Köttig et al. (2012) and the quoted literature there).

In general, the effort to understand how ordinary people deal with situations of societal and global crisis, ethnicized social conflicts, war and trauma, and violence, abuse, and disappearance (Germano, 2013) has been, and still is, a core topic in biographical research. Insights on how these experiences shape people's lives, how they are part of social contexts by the way in which those affected orient and act based on their experiences (which are formed and change over a longer period of time), and how they mold different generations and their mutual relations are specific contribution from biographical research. Thus, biographical research is closely part of and connected with general processes of societies have to deal with the aftermath of war, genocide, and collective violence in different parts of the world.

Collective Identities

Associated with these research topics, interest in collective identities and how they develop in situations of transforming societies has expanded during the last 10 years. The concept of ethnicity and its significance in biographies has been widely scrutinized (Apitzsch, 2012b; Rosenthal and Bogner, 2009). Seen from a biographical perspective, ethnicity is no longer conceptualized as an ascribed characteristic of a specific group, even if a group identifies itself ethnically, but is seen as something which is created and revised in biographical processes in which the significance of ethnicity is negotiated in majority–minority relations, in family and generational relations, and within a social community. Its meaning thus can vary and change, e.g., from a marginal social position due to an ascribed belonging, which hinders social mobility, to a biographical resource to overcome discrimination.
